EXECUTIVE SUMMARY

The Ventura County Air Pollution Control District (VCAPCD) provides guidelines for conducting health risk assessments (HRAs) related to freeway emissions, particularly when sensitive land uses are proposed near heavily traveled transportation corridors.

According to the Ventura County General Plan, discretionary developments that include sensitive receptors should be located at least 1,000 feet from road with traffic volumes exceeding 50,000 vehicles per day. If a project proposes sensitive land uses within this 1,000-foot buffer, a site specific HRA is required. The Ventura Ranch Farmworker Housing Community Project (Project) is located approximately less than 150 feet east of State Route 33 (SR-33). Therefore, the purpose of this HRA is to provide an assessment of the impacts resulting from the proposed Project and to identify any measures that may be necessary to reduce potentially significant impacts.

The analysis indicates that without the installation of any filters, cancer risk impacts would remain below the applicable significance threshold. Thus, the cancer and chronic risk for residential receptors due to SR-33 would not be considered significant for all residential receptors at the Project site. However, to further reduce the exposure of the Project's on-site residents to Diesel Particulate Matter (DPM) emissions, it is recommended that the Project incorporate high-efficiency pleated particle filters for residential uses located near busy roadways. These filters are generally considered the most effective approach to filtration because they can remove the very small particles emitted by motor vehicles without emitting ozone, formaldehyde, or other harmful byproducts.

Minimum Efficiency Reporting Value (MERV) filters would generally be considered the most effective approach to filtration because these filters can remove the very small particles emitted by motor vehicles without emitting ozone, formaldehyde, or other harmful byproducts. MERV 13 air filtration systems are capable of removing 50 percent or more of particles between 0.3 and 1.0 microns, often used in commercial buildings, residential heating, ventilation and air conditioning (HVAC) systems, and hospitals.

PROJECT DESCRIPTION

Overview

The proposed Ventura Ranch project is a comprehensive residential community exclusively for farmworkers and their families, located north of the city of Ventura near the major agricultural regions of the Oxnard Plain. The community will consist of 308 apartments, along with community spaces such as two indoor community centers, play fields, plazas, walking paths, and playgrounds. The site will also contain infrastructure such as driveways and parking areas, utility improvements, and other associated infrastructure.

Ventura Ranch is designed with the goal of providing a high quality, attractive, and safe environment for its residents. The community will consist of one-, two-, and three-bedroom apartments in a Spanish Colonial style, ranging approximately from 576 to 1,104 square feet in size. Each apartment will have a private outdoor living space, such as a patio or balcony. Apartment buildings will be oriented towards central outdoor spaces. Sustainability will also be emphasized, with all electric energy efficient appliances, native landscaping, and on-site stormwater treatment and management. Ventura Ranch will provide 308 new affordable dwelling units exclusively to farmworkers and their families in accordance with Ventura County Non-Coastal Zoning Ordinance Section 8107-41.1.

Project Site

The Project site is located at 4884 N. Ventura Avenue within unincorporated Ventura County, north of the city of Ventura and approximately less than 150 feet east of SR-33, as shown in **Figure 1: Project Site Location**. The project will include a 4 lot Tentative Parcel Map of an existing 82.9-acre legal lot that consists of APNs 063-0-110-06, -03, -09 and -14. The farmworker housing development will consist of two parcels; Parcel One is 9.5 acres and Parcel Two is 8.59 acres. The existing farmhouse and barn on the property will remain on a 10.67-acre parcel identified as the agricultural parcel (Parcel Three) and Parcel Four is a 54.14-acre parcel that will be designated a Conservation Subdivision lot and will be donated to a conservation entity.

The applicant is requesting the property be subdivided into four parcels. Two parcels will be developed for farmworker housing, and one will contain the existing residence, barn and a total of 10.67 acres. The fourth lot will consist of the remaining undeveloped open space property. The two farmworker housing development parcels will consist of 308 residential units and two community centers developed in two phases of approximately equal size.

Proposed Site Design

The proposed farmworker housing community will contain 308 dwelling units, along with amenities such as community center room(s), play fields, tot lots/playgrounds, and barbeque areas. The project will be developed in two phases as detailed in **Figure 2: Conceptual Site Plan** and **Figure 3: Tentative Parcel Map**. The site takes access from a driveway off of Ventura Road and from the extension of Floral Drive

from the Norway Tract to the north of this site. These proposed access roads meet Ventura County Road standards. Access and utility easements for the benefit of all parcels are shown in **Figure 3**.

Circulation within the community is provided by a looping driveway that meets fire aerial apparatus standards, and provides vehicular circulation to the proposed units, as well as resident parking spaces. The proposed parcels will be granted access easements over the proposed driveway, to ensure complete site circulation. The proposed residential units are clustered in the center of the site, overlooking core community spaces such as play fields, playgrounds, and community centers. Internal pathways provide pedestrian circulation to residential buildings and community amenities within the site.

Preliminary unit composition consists of a blend of one-, two-, and three-bedroom units. Unit sizes range from approximately 575 to 1,100 square feet. In addition to these residential units, two 3,000 square foot community centers are proposed.

Five different residential building types are proposed. Building Types A, B, C and E can best be described as three-story apartment buildings, each containing 12 to 24 dwelling units. Building Type D is a two-story quadplex type building.

ENVIRONMENTAL SETTING

Ambient air quality emissions present complex environmental issues that require regulatory attention on both large and small scales. The cumulative nature of project-level and localized emissions contributing to greater regional conditions warrants that regulatory policies be instituted on national, State, and regional levels to address air quality concerns. The following sections outline the applicable regulatory framework that exists at the national, State, and regional levels for air quality.

Background

The United States Environmental Protection Agency (USEPA) is responsible for federal oversight and enforcement of air quality management policies under the 1970 Clean Air Act (CAA). Each individual state is tasked with preparing and adhering to State Implementation Plans[1] (SIPs) for achieving the goals set forth within the CAA. California has some of the most stringent air quality policies in the country and, through the California Air Resources Board (CARB) branch of the California Environmental Protection Agency (CalEPA), has developed its own ambient air quality standards (AAQS). The State is divided into air quality jurisdictions; each jurisdiction is governed by a regional air district that oversees policy implementation, permitting of air pollution emission sources, and enforcement of regulatory requirements. Six criteria air pollutants (CAPs) are monitored at the federal, State, and regional levels. These six CAPs—ozone, particulate matter PM10 and PM2.5, nitrogen dioxide, carbon monoxide, lead, and sulfur dioxide—were identified based on a consensus of decades of research that concluded inhalation of each of the chemicals results in adverse health effects in humans. The six pollutants are identified below in **Table 1: Sources and Health Effects of Criteria Air Pollutants**, along with their common sources and primary health effects from inhalation exposure.

1 A State Implementation Plan is a document prepared by each state describing existing air quality conditions and measures that will be followed to attain and maintain National Ambient Air Quality Standards.

TABLE 1: SOURCES AND HEALTH EFFECTS OF CRITERIA AIR POLLUTANTS		
Pollutants	**Sources**	**Primary Effects**
Ozone (O3)	Formed through chemical reactions between pollutants emitted from vehicles, factories and other industrial sources, fossil fuels, combustion, consumer products, evaporation of paints, and many other sources; VOCs and NOx react in the presence of sunlight	Respiratory symptoms; worsening of lung disease; lung tissue damage; ecosystem damage; damage to rubber and some plastics
Respirable particulate matter (PM10)	Emissions from combustion of gasoline, oil, diesel fuel or wood; dust from construction sites, landfills and agriculture, wildfires and brush/waste burning, industrial sources, wind-blown dust from open lands, pollen, and fragments of bacteria; chemical reactions of gases and certain organic compounds	Premature death and hospitalization; worsening of respiratory disease; reduced visibility; surface soiling
Fine particulate matter (PM2.5)	Emissions from combustion of gasoline, oil, diesel fuel or wood; chemical reactions of gases and certain organic compounds	Premature death; hospitalization; asthma-related emergencies; increased asthma symptoms and inhaler use
Carbon monoxide (CO)	Incomplete combustion of CO-containing fuels such as natural gas, gasoline, or wood; emitted by a wide variety of combustion sources, including motor vehicles, power plants, wildfires, and incinerators	Chest pain in heart disease patients; headaches; light-headedness; reduced mental alertness
Nitrogen dioxide (NO2)	Emitted from combustion sources similar to CO; formed in the atmosphere through reactions between NO and other air pollutants that require the presence of sunlight (photochemical reactions).	Lung irritation; enhanced allergic responses
Lead (Pb)	Present in soils; ore and metals processing; waste incinerators, utilities, and lead-acid battery manufacturers	Impaired mental function; learning disabilities; brain and kidney damage
Sulfur dioxide (SO2)	Emitted when sulfur-containing fuel is burned; industrial processes, such as natural gas and petroleum extraction, oil refining, and metal processing; volcanic activity and from geothermal fields	Worsening of asthma: increased symptoms, increased medication usage, and emergency room visits; acid rain

USEPA is the federal agency responsible for overseeing the country's air quality and setting the NAAQS for the CAPs. The NAAQS were devised based on extensive modeling and monitoring of air pollution across the country; they are designed to protect public health and prevent the formation of atmospheric ozone. Air quality of a region is considered to be in attainment of the NAAQS if the measured ambient air pollutant levels do not exceed the applicable concentration threshold.

As noted previously, CARB is the State agency responsible for setting the CAAQS. Air quality of a region is considered to be in attainment of the CAAQS if the measured ambient air pollutant levels for O3, CO, NO2, SO2, PM10, PM2.5, and Pb are not exceeded, and all other standards are not equaled or exceeded at any time in any consecutive 3-year period. The CAAQS are also presented in **Table 2**.

The nearest air monitoring station VCAPCD operates is the Ojai monitoring location at 1201 E. Ojai Avenue. This station monitors O3 and PM2.5. **Table 2: Air Quality Monitoring Summary** summarizes published monitoring data from 2020 through 2022, the most recent 3-year period available. The data shows that during the past few years, the region has exceeded the O3 and PM2.5 standards.

USEPA and the CARB designate air basins where AAQS are exceeded as "nonattainment" areas. If standards are met, the area is designated as an "attainment" area. If there is inadequate or inconclusive data to make a definitive attainment designation, they are considered "unclassified." Federal nonattainment areas are further designated as marginal, moderate, serious, severe, or extreme as a function of deviation from standards.

TABLE 2: AIR QUALITY MONITORING SUMMARY

Air Pollutant	Average Time (Units)	2020	2021	2022
Ozone (O3)	State Max 1 hour (ppm)	0.092	0.078	0.079
	Days > CAAQS threshold (0.09 ppm)	0	0	0
	National Max 8 hour (ppm)	0.083	0.068	0.073
	Days > NAAQS threshold (0.075 ppm)	8	0	3
	State Max 8 hour (ppm)	0.084	0.068	0.074
	Days > CAAQS threshold (0.07 ppm)	8	0	3
Fine particulate matter (PM2.5)	National Max (µg/m3)	33.0	20.6	15.5
	National Annual Average (µg/m3)	6.5	6.1	5.5
	Days > NAAQS threshold (35 µg/m3)	0	0	0
	State Max (µg/m3)	33.0	20.6	15.5
	State Annual Average (µg/m3)	6.6	6.2	5.6

Source: CARB, iADAM: Air Quality Data Statistics.

The current attainment designations for the Ventura County portion of the Basin are shown in **Table 3: Air Basin Attainment Status**. The Basin is currently designated as being in nonattainment at the federal level for O3 and at the State level for O3 and PM10.

TABLE 3: AIR BASIN ATTAINMENT STATUS

Pollutant	State Status	National Status
Ozone (O3)	Nonattainment	Nonattainment
Carbon monoxide (CO)	Attainment	Unclassified/Attainment
Nitrogen dioxide (NO2)	Attainment	Unclassified/Attainment
Sulfur dioxide (SO2)	Attainment	Unclassified/Attainment
Respirable particulate matter (PM10)	Nonattainment	Unclassified/Attainment
Fine particulate matter (PM2.5)	Attainment	Unclassified/Attainment

The USEPA sets national vehicle and stationary source emission standards; oversees approval of all SIPs; provides research and guidance for air pollution programs; and sets National Ambient Air Quality Standards (NAAQS). The NAAQS for the six CAPs are shown in **Table 4: Ambient Air Quality Standards** and were identified from provisions of the 1970 CAA. The sections of the CAA that are most applicable to the Project include Title I: Nonattainment Provisions and Title II: Mobile Source Provisions.

TABLE 4: AMBIENT AIR QUALITY STANDARDS

Pollutant	Averaging Time	California Standards		Federal Standards		
		Concentration	Method	Primary	Secondary	Method
Ozone (O3)	1 hour	0.09 ppm (180 µg/m^3)	Ultraviolet photometry	—	Same as primary standard	Ultraviolet photometry
	8 hours	0.07 ppm (137 µg/m^3)		0.075 ppm (147 µg/m^3)		
Respirable particulate matter (PM10)	24 hours	50 µg/m^3	Gravimetric or beta attenuation	150 µg/m^3	Same as primary standard	Inertial separation and gravimetric analysis
	Annual arithmetic mean	20 µg/m^3		—		
Fine particulate matter (PM2.5)	24 hours	No separate State standard		35 µg/m^3	Same as primary standard	Inertial separation and gravimetric analysis
	Annual arithmetic mean	12 µg/m^3	Gravimetric or beta attenuation	15 µg/m^3		
Carbon monoxide (CO)	8 hours	9.0 ppm (10 mg/m^3)	Nondispersive infrared photometry (NDIR)	9 ppm (10 mg/m^3)	None	NDIR
	1 hour	20 ppm (23 mg/m^3)		35 ppm (40 mg/m^3)		
Nitrogen dioxide (NO2)	Annual arithmetic mean	0.03 ppm (57 µg/m^3)	Gas phase chemilumi-nescence	0.053 ppm (100 µg/m^3)	Same as primary standard	Gas phase chemilumi-nescence
	1 hour	0.18 ppm (339 µg/m^3)		0.100 ppm (188 µg/m^3)		

Source: California Air Resources Board website at: http://www.arb.ca.gov/research/aaqs/aaqs.htm. Accessed June 2023.
Note: ppm = parts per million.

The CAA and the promulgated standards have evolved as a living document over time as research into the effects of air pollution has enhanced regulatory understanding of the associated issues. The 1990 amendments to the CAA identify specific emission reduction goals for areas not meeting the NAAQS. These amendments require both a demonstration of reasonable further progress toward attainment and incorporation of additional sanctions for failure to attain or to meet interim milestones. On the national level, the USEPA designates regions as achieving "attainment" or suffering from "nonattainment" of the NAAQS based on air quality monitoring data. Regions that are designated as being in nonattainment are

responsible for devising localized strategies for reducing emissions of CAPs and achieving regional attainment within a predetermined timeframe set by the USEPA.

The NAAQS were further amended in July 1997 to include an 8-hour standard for ozone and to adopt an NAAQS for PM2.5. The NAAQS were amended again in September 2006 to include an established methodology for calculating PM2.5, as well as to revoke the annual PM10 threshold. Additional revisions to the AAQS may be implemented in the future as the science of air quality progresses.

State

The California Clean Air Act, signed into law in 1988, requires all areas of the State to achieve and maintain the California Ambient Air Quality Standards (CAAQS) by the earliest practicable date. CARB is responsible for the coordination and administration of both State and federal air pollution control programs within California. In this capacity, CARB conducts research, sets CAAQS, compiles emission inventories, develops suggested control measures, and provides oversight of local programs.

CARB establishes emissions standards for motor vehicles sold in California, consumer products, and various types of commercial equipment. It also sets fuel specifications to further reduce vehicular emissions and the CAAQS currently in effect for each of the criteria pollutants, as well as other pollutants recognized by the State. The CAAQS are provided in **Table 4**. It should be noted that the CAAQS are generally more stringent than the NAAQS, reflecting California's diligent efforts toward reducing air pollution and improving air quality.

METHODOLOGY

The methodologies and assumptions used for the HRA analysis are consistent with the guidance recommended by the California Environmental Protection Agency's Office of Environmental Health Hazard Assessment (OEHHA) Air Toxic Hot Spots Program Risk Assessment Guidelines.[2] The methodology used in this assessment uses a dose-response assessment to characterize risk from cancer due to inhaled toxic air contaminants (TACs) and the assessment of acute and chronic noncancer from diesel particulate matter (DPM). Based on the OEHHA guidance, the evaluation of potential health risks uses the following standard four-step risk assessment process: (1) Hazard Identification; (2) Exposure Assessment; (3) Dose-Response Assessment; and (4) Risk Characterization.

Hazard Identification

The hazard identification process is undertaken to determine what TACs are potentially present in the assessment areas, and if so, identified what the pollutants of concern are along with their potential adverse health effects. In this HRA, the primary hazard is DPM emissions from vehicular sources (specifically diesel-powered trucks) along the SR-33 freeway corridor, which is located less than 150 feet west of the proposed Project. CARB identified DPM as a TAC with potential cancer and chronic non-cancer effects.

DPM historically has been used a surrogate measure of exposure for whole diesel exhaust emissions. Diesel exhaust is a complex mixture of thousands of gases and fine particles (commonly known as soot). Diesel exhaust particles and gases are suspended in the air due to thermal buoyancy and the small size of the particles. The composition of diesel exhaust varies depending on engine type, operating conditions, fuel composition, lubricating oil, presence of an emission control system. One of the main characteristics of diesel exhaust is the release of particles at a relative rate approximately 20 times greater than from gasoline-fueled vehicles, on an equivalent fuel basis. Diesel particulates are mainly aggregates of spherical carbon particles coated with inorganic and organic substances. The inorganic fraction primarily consists of small carbon (elemental carbon) particles ranging from 0.01 to 0.08 micron in diameter. The organic fraction consists of soluble organic compounds.

Exposure Assessment

The degree of the Project's exposure to DPM from existing vehicle traffic on SR-33 was evaluated under the exposure assessment portion of the HRA. This assessment starts with the quantification of DPM emissions, followed by dispersion modeling and an estimation of long-term exposure levels. The amount of DPM emissions generated by vehicle traffic on SR-33 was determined using PM10 from diesel exhaust as a surrogate.

2 OEHHA, *Air Toxic Hot Spots Program Risk Assessment Guidelines*, February 2015.

Detailed Modeling

Air dispersion modeling was conducted using the American Meteorological Society/Environmental Protection Agency Regulator Model (AERMOD). This model is a steady-state, multiple-source, Gaussian dispersion model designed for use with emission sources situated in terrain where ground elevations can exceed the release heights of the emission sources (i.e., complex terrain). AERMOD is the U.S. EPA's regulatory dispersion model specified in the Guideline for Air Quality Methods.[3] AERMOD is recommended for use by the Ventura County Air Pollution Control District (VCAPCD), which has established its own modeling guidance for the model.

Emission Sources

Within AERMOD, diesel vehicle traffic was modeled as a line source comprised of separate volume sources along the stretch of SR-33 that is located to the west of the Project site, as shown in **Figure 4: Emission Source and Receptor Grid Map**. Diesel exhaust emissions were modeled using a release height of 7.41 feet (2.26 meters), which is the weighted average height of an exhaust stack above ground level for the combined diesel car and truck traffic along this stretch of freeway. The plume height and width used for each volume sources was 14.83 feet and 31.37 feet (4.52 and 14.23 meters), respectively. Based on guidance, the plume height was determined by multiplying the average stack height by a factor of 2, while the plume width was determined by adding 19.69 feet (6 meters) to the lane width.

Emission Rates

The quantification of diesel exhaust emissions requires the definition of a diesel exhaust emission rate (in grams per second) for trucks. To estimate this emission rate, emission factors (in grams per mile) for various vehicle classes of diesel-powered trucks and cars were first obtained from the EMFAC web database. Pollutant emission rates were identified for total organic gases (TOG), diesel particulates, particulates (PM10 and PM2.5), carbon monoxide (CO) and nitrogen oxide (NOx) compounds. Using these emission factors and the available average daily vehicle traffic counts published by the California Department of Transportation (Caltrans) along with the distance of the SR-33 corridor to be modeled, the total grams of diesel exhaust emissions that would be generated along the SR-33 segment to be modeled were obtained. In turn, the total emissions amount was then converted into an exhaust emission rate in grams per second.

A conservative route speed of 65 miles per hour (mph) was assumed for the northbound and southbound lanes on SR-33.

For particulates (PM10 and PM2.5), emissions were quantified through the reentrainment of paved roadway dust. The predictive emission equation developed by the U.S. Environmental Protection Agency (AP-42, Section 13.2.1) was used to generate particulate source strength. To account for the mass rate

3 U.S. EPA Code of Federal Regulations, Title 40, Part 51, Appendix W

emissions entrained from the roadway surface, the contribution from exhaust, break and tire wear were added to the AP-42 emission factor equation.

Within AERMOD, the emission rate used for dispersion modeling assumed a rate of 1.0 gram per second for the entire line source. The use of a unitary emission rate (1.0 gram per second) allows for the AERMOD results to be factored based on actual emission rates that are calculated and outlined in the aforementioned steps. For example, assume that an emission rate of 1 gram per second results in a dispersion modeling concentration of 0.5 $\mu g/m^3$. Using these results, an actual emission rate of 5 grams per second would result in a concentration of 2.5 $\mu g/m^3$ (5 grams per second/gram per second x 0.5 $\mu g/m^3$ equals 2.5 $\mu g/m^3$). This approach is useful as any future changes that are necessary in the calculation of emission rates would not require the AERMOD to be run again to obtain the actual TAC concentration.

Meteorological Data

In order to run AERMOD, the following hourly surface meteorological data are required: wind speed, wind direction, ambient temperature, and opaque cloud cover. These meteorological variables are used to estimate air dispersion of pollutants in the atmosphere. Wind speed determines how rapidly pollutants are diluted and influences the rise of the emission plume in the air, thus affecting downwind pollutant concentrations. Wind direction determines where pollutants will be transported. The opaque cloud cover and upper air surrounding data are used in calculations to determine other important dispersion parameters. These include atmospheric stability (a measure of turbulence and the rate at which pollutants disperse laterally and vertically) and mixing height (the vertical depth of the atmosphere within which dispersion occurs). The greater the mixing height is, the larger the volume of atmosphere is available to dilute the pollutant concentration.

The dispersion modeling for the Project utilized pre-processed meteorological data from the El Rio Monitoring Station. The meteorological data was collected for the years between 2015 through 2019.

Sensitive Receptors

In order to determine the DPM concentrations at the Project site, discrete receptors were placed inside the boundary of the Project site at areas where future residential units would be located (refer to **Figure 4**). In order to meet VCAPCD's requirements and accurately characterize the risk throughout the Project site, a 32.81 foot by 32.81 foot (10 meter by 10 meter) receptor grid was placed over the Project site (including site boundaries). The receptor grid was then converted to discrete receptors to maintain spacing and provide for ease in determining the maximum exposed individual (MEI).

Terrain Data

The modeling analysis also included terrain data to accurately assess impacts in three dimensions. The terrain data used for the analysis was from the digital elevation model data for the 7.5-minute quadrangles obtained through the AERMOD program.

Urban/Rural

The AERMOD model requires that the user specify whether a site should be modeled as either urban or rural. The urban option allows the user to incorporate the effects of increased surface heating from an urban area on pollutant dispersion under stable atmospheric conditions. This surface heating typically causes better dispersion, which results in lower pollutant concentrations.

Based on VCAPCD's AERMOD modeling guidance, all air quality impact analyses in the Basin should be executed using the urban modeling option. In addition, all sources should be modeled with urban effects using the population of the County where the Project is located. As VCAPCD provides the various County populations within AQMD jurisdiction, the population of 109,925 for the City of Ventura was used in the AERMOD run.

Dose-Response Assessment

The dose-response assessment is the process of characterizing the relationship between exposure to diesel exhaust and the incidence of an adverse health effect in the exposed populations.

The estimation of potential inhalation cancer risk posed by exposure to DPM requires a cancer potency factor. Cancer potency factors are expressed as the upper bound probability of developing cancer assuming continuous lifetime exposure to diesel exhaust at a dose of one milligram per kilogram of body weight and are expressed in units of inverse dose as a potency slope (i.e., $[mg/kg/day]^{-1}$). A cancer potency factor when multiplied by the dose of a carcinogen gives the associated lifetime cancer risk. The cancer potency factor for DPM is 1.1 $(mg/kg/day)^{-1}$.[4] The estimation of potential inhalation chronic non-cancer effects posed by exposure to DPM requires a chronic reference exposure level (REL). A chronic REL is a concentration level (that is expressed in units of micrograms per cubic meter [$\mu g/m^3$] for inhalation exposures), at or below which no adverse health effects are anticipated following long-term exposure. The chronic REL for DPM is 5 $\mu g/m^3$.[5] The chronic hazard index target organ for DPM is the respiratory system.

Risk Characterization

Risk characterization combines the maximum annual average ground-level DPM concentration from the exposure assessment and the cancer potency factor and chronic REL from the dose-response analysis to

5 California Environmental Protection Agency Office of Environmental Health Hazard Assessment, *Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments*, August 2003.

estimate the potential inhalation cancer risk and chronic hazard index (HI) from the exposure to DPM emissions.

For the Project's health risk evaluation, the maximum exposed individual (MEI) was assumed to reside at the same receptor location for 30 years. This is a conservative assumption because typically speaking, people no longer spend their entire life in one location.

The equation used to calculate the potential excess lifetime cancer risk for the residential inhalation pathway is as follows:

$$Dose = (C_{air} \times DBR \times A \times EF \times ED \times CF) / AT$$

Where:

Dose = Dose through inhalation (milligrams per kilogram-day [mg/kg/day])
C_{air} = Concentration of DPM in air (micrograms per cubic meter [µg/m^3] – from AERMOD)
DBR = Daily breathing rate, or the average amount of air inhaled daily (liters per kilograms body weight-day [L/kg body weight-day]) = 302 L/kg)
A = Inhalation absorption factor (unitless), the potential for absorption into the body through the lungs = 1.
EF = Exposure frequency (days per year [days/yr]) = 350 days/year.
ED = Exposure duration (years[yr]) = 30 years
CF = Composite conversion factor (micrograms per cubic meters – milligram per 1,000 liter [mg/µg x m^3/L]) = 1 x 10^{-6}
AT = Averaging time period over which exposure is averaged (number of days over the total exposure period. For lifetime cancer risk, the averaging time is 30 regardless of the exposure duration.) = 10,958 days

The following equation was used to estimate the excess cancer risk for a resident at the Project based upon the calculated dosage:

$$Cancer\ Risk = Dose\ X\ CPF$$

Where:

Cancer Risk = Risk (potential chances per million)

Dose = Dose from inhalation (mg/kg-day)

CPF = Chemical or compound cancer potency factor = (1 mg/kg-day^{-1})

Finally, the potential non-cancer health risk for chronic exposure to DPM was evaluated by calculating the Hazard Quotient (HQ) using the following equation:

$$HQ = C_{airi}/REL$$

Where:

HQ = Hazard quotient for DPM (unitless)

C_{airi} = Increase in average annual PM10 concentration ($\mu g/m^3$) from air dispersion model at the MEI

REL = Reference exposure level for DPM (5 $\mu g/m^3$)

Emission Source and Receptor Grid Map

391-001-23

SIGNIFICANCE THRESHOLDS

Most projects do not involve generation of a substantial source of TACs. Those that would emit TACs are subject to the permit authority of the VCAPCD and the analysis of any TACs and their potential impact should be coordinated with the VCAPCD permit requirements. One source of TACs that is not directly regulated by the VCAPCD is diesel exhaust from heavy trucks. If a project would create a major concentration of heavy truck traffic for a long period of time or involves sensitive receptors that may be exposed to substantial concentrations of truck traffic or other sources of TACs (e.g., within 500 feet of SR-33), then the toxic effects of diesel particulate matter may be of concern. If TACs are a concern, then a health risk assessment (HRA) may need to be conducted. The HRA involves the use of an air quality dispersion model and procedures and input values approved by the VCAPCD. The following criteria are used to determine the significance of a potential health risk impact:

- For cancer causing contaminants: a lifetime probability of contracting cancer is greater than 10 in one million as identified in the HRA.
- For non-carcinogenic pollutants: a Hazard Index of greater than 1, as identified in the HRA.

According to CARB's Air Quality and Land Use Handbook, sources that may cause health risks to nearby sensitive receptors include freeways, distribution centers, rail yards, ports, refineries, chrome platers, dry cleaners, and gasoline disposing facilities. The Project would construct a multi-family residential building adjacent to the SR-33 freeway. Therefore, a quantitative operational HRA was conducted to assess diesel particulate matter (DPM) from the freeway to the proposed residences.

As shown in **Table 5: Estimated Inhalation Cancer Risk and Chronic Hazards**, for the maximum exposed residential units (MEIR), results of the analysis predicted freeway emissions would not result in cancer risks above the significance criterion of 10 per 1 million. The chronic health impact would be less than 1 (0.00421) and would be below the Project-level threshold of 1.

TABLE 5: ESTIMATED INHALATION CANCER RISK AND CHRONIC HAZARDS

Receptor	DPM Concentration at Exposed Receptor ($\mu g/m^3$)	Cancer Risk at Maximum Exposed Receptor (risk/million)	VCAPCD Cancer Risk Significance Threshold (risk/million)	Exceeds Threshold?	Chronic Non-Cancer Hazard Index	VCAPCD Non-Cancer Hazard Index Significance Threshold?	Exceeds Threshold?
Resident MEIR	4.2E-03	3.64E-06[3]	1.0E-05	**No**	4.21E-03[3]	1.0	No

Note:

*[1] Refer to **Appendix 1.0** for AERMOD Output Sheets which provides modeling inputs.*

*[2] Refer to **Appendix 2.0** for Emission Rate Worksheets which provides modeling inputs.*

*[3] Refer to **Appendix 3.0** for Cancer Risk Worksheets.*

As identified in the Ventura County General Plan, to further reduce the exposure of the Project's on-site residents to DPM emissions, the Project can incorporate the following design features to further reduce potential cancer risk:

- Installing air intakes furthest away from the heavily traveled transportation corridor
- Installing air filtration (as part of mechanical ventilation systems or standalone air cleaner);
- Using air filtration devices rated MERV-13 or higher;
- Requiring ongoing maintenance plans for building HVAC air filtration systems;
- Limiting window openings and window heights on building sides facing the heavily traveled transportation corridor; or
- Permanently sealing windows so they don't open on the side of the building facing the heavily traveled transportation corridor; and installing vegetative barriers, considering height and cover thickness, to create a natural buffer between sensitive receptors and the emissions source.

CERTIFICATION

The contents of this Mobile HRA represent an accurate depiction of the environment and impacts associated with the proposed Ventura Ranch Farmworker Housing Community Project. The information contained in this noise study is based on the best available information at the time of preparation. If you have any questions, please contact me directly at (818) 415-7274.

Summary

The applicant proposes a tentative parcel map to create four parcels, and construct farmworker housing on newly created Parcels 1 and 2 (19.59 acres). The farmworker housing would include 328 apartments, along with community spaces such as two indoor community centers, a teen/adult recreational amenity (such as a basketball court), play fields, community garden, walking paths, and playgrounds. The site will also contain infrastructure such as driveways and parking areas, utility improvements, and other associated infrastructure. An agricultural parcel of 10.02 acres will remain as Parcel 3 and Parcel 4 (53.31 acres) would be created that would remain undeveloped open space and will be designated a Conservation Subdivision lot. Parcel 4 would be owned by a conservation entity.

Potentially significant impacts are limited to removal of seven protected trees and potential take of nesting migratory birds due to vegetation removal and construction activity. Mitigation measures are provided that would reduce impacts to a level of less than significant.

Rincon Consultants, Inc. reviewed the draft ISBA (dated July 22, 2024) on behalf of the Ventura County Planning Division and provided a comment letter dated February 24, 2025, which was provided to Padre Associates on March 11, 2025. A summary of these comments and responses are provided below.

Comment 1. Include proposed improvements (walking paths, hiking trails and parking area within Parcel 4, community gardens, basketball courts, play fields, landscaping) on the ISBA figures.

Response: A new figure (numbered as Figure 5) has been added which provides a project site plan (taken from the Preliminary Grading Plan) showing all proposed improvements. Note that there are no hiking trails or other amenities proposed outside the project footprint shown on Figure 5.

Comment 2. Complete Combined Vegetation Rapid Assessment and Relevé Field Forms for all sensitive vegetation communities observed within the survey area and submit the forms to the California Department of Fish and Wildlife (CDFW).

Response: These forms were completed in the field on April 23, 2025 and are attached to this revised ISBA. The forms were submitted to CDFW on April 24, 2025.

Comment 3. Vegetation community polygons in Figure 3 immediately north and northeast of the Parcel 3 boundary are currently merged together. The green vegetation lines that separate PC1, PC2, and PC17 currently terminate at the "Proposed Internal Parcel Boundary" and should be revised to address this inconsistency.

Response: Vegetation mapping has been revised to provide closed polygons for each mapping unit.

Comment 4. Tree No. 3 in the ISBA is actually a blue spruce (*Picea pungens*) tree. In addition, five additional County protected trees were identified within the grading footprint, including two coast live oaks (*Quercus agrifolia*), two canary island date palms (*Phoenix canariensis*), and one blue gum eucalyptus (*Eucalyptus globulus*). An arborist survey and report should be prepared and submitted to the County.

Response: An Arborist Report has been prepared by Cragoe Pest Services and is attached to this revised ISBA. Note that the date palms are not considered protected as they are less than 60 feet tall and 75 years old (see Tree Protection Regulations, NCZO Section 8107-25.2). The text and Figure 2 (tree numbers and locations) of the ISBA have been revised to be consistent with the findings of the Arborist Report.

Comment 5. Several special status species are documented in the CDFW California Natural Diversity Database (CNDDB) within five miles of the project site, but are not included in the special-status species table on Page 25 of the ISBA. Evaluate the potential for occurrence and impacts to these species, and include mitigation measures if it is determined that any of the species have the potential to be impacted by the project:

Response: The ISBA has been revised to evaluate the potential for occurrence and impacts to these species.

Comment 6. Please include all wildlife barriers described on Page 30 of the ISBA on project figures.

Response: Potential wildlife barriers (fencing) described under connectivity features have been added to Figures 3 and 4 of this revised ISBA.

Section 1: Construction Footprint Description

Construction Footprint Definition (per the Ventura County Planning Division): The construction footprint includes the proposed maximum limits of direct land disturbance for the project including such things as the building pad(s), roads/road improvements, grading, septic systems, wells, drainage improvements, fire hazard brush clearance area(s), storage/stockpile areas, construction staging areas, fire department turnarounds, utility trenching and other grading areas. The construction footprint on some types of projects, such as mining, oil and gas exploration or agricultural operations, may be quite different than the above.

Development Proposal Description

The applicant proposes to construct farmworker housing on two newly created Parcels 1 and 2 (totaling 19.59 acres), including 328 apartments, along with community spaces such as two indoor community centers, a teen/adult recreational amenity (such as a basketball court), play fields, community garden, walking paths, and playgrounds. The other two newly created parcels (Parcels 3 and 4, totaling 53.31 acres) would remain undeveloped open space and will be designated a Conservation Subdivision lot. A site plan showing all proposed improvements as shown on the Preliminary Grading Plan has been provided as Figure 5.

Utilities would be provided from existing service lines along Ventura Avenue. No ground disturbance outside Parcels 1 and 2 would be required for installation of utilities. Fuel modification areas (100 feet from proposed residences, see Figure 2) would extend approximately 25 feet to the south (onto APNs 063-0-131-010, -020) but would remain within the proposed grading limits. Construction staging would be limited to proposed Parcels 1 and 2 and the undeveloped parcel (fallow farmland) to the south.

Construction Footprint Size

Grading and related earthwork total approximately 17 acres of ground disturbance as shown on the Site and Survey Map (grading limits). The Preliminary Grading Plan indicates the development would require approximately 29,000 cubic yards of cut, 46,000 cubic yards of fill, 23,000 cubic yards of over-excavation with 17,000 cubic yards of imported earth material.

Project Design for Impact Avoidance or Minimization

All proposed development would be located within fallow farmland and not result in the loss of any native vegetation or native trees.

Overlay Zones

None.

Zoning

AE-40 ac (proposed Parcels 1 and 2) and OS-160 ac (proposed Parcels 3 and 4).

Elevation

Elevation across the property ranges from approximately 700 feet in the eastern portion of proposed Parcel 4 to approximately 200 to 230 feet at Parcels 1 and 2.

Section 2: Survey Information

2.1 Survey Purpose

The purpose of this Initial Study Biological Assessment (ISBA) is to gather enough information about the biological resources associated with the proposed project, and their potential to be impacted by the project, to make a CEQA (California Environmental Quality Act) Initial Study significance finding for biological resources. In general, ISBA's are intended to:

- Provide an inventory of the biological resources on a project site and the values of those resources.
- Determine if a proposed project has the potential to impact any significant biological resources.
- Recommend project redesign to avoid, minimize or reduce impacts to significant biological resources.
- Recommend additional studies necessary to adequately assess potential impacts and/or to develop adequate mitigation measures.
- Develop mitigation measures, when necessary, in cases where adequate information is available.

2.2 Survey Area Description

Survey Area Definition (per the Ventura County Planning Division): The physical area a biologist evaluates as part of a biological assessment. This includes all areas that could potentially be subject to direct or indirect impacts from the project, including, but not limited to: the construction footprint; areas that would be subject to noise, light, dust or runoff generated by the project; any required buffer areas (e.g., buffers surrounding wetland habitat). The construction footprint plus a 100-foot buffer—beyond the required fire hazard brush clearance boundary—(or 20-foot from the cut/fill boundary or road fire hazard brush clearance boundary – whichever is greater) is generally the minimum size of a survey area. Required off-site improvements—such as roads or fire hazard brush clearance—are included in the survey area. Survey areas can extend off the project's parcel(s) because indirect impacts may cross property lines. The extent of the survey area shall be determined by the biologist in consultation with the lead agency.

Survey Area 1 (SA1)

The 63.0-acre Survey Area 1 encompassed about 50 acres of the 82.92-acre property.

Location

Survey Area 1 is located in the Ventura River valley, just east and south of a single-family residential area between Norway Drive and Floral Drive, and approximately 0.3 miles east of the Ventura River. Proposed Parcel 1 is located adjacent to Ventura Avenue (see Figure 2).

Survey Area Boundaries

Survey Area 1 encompassed all of proposed Parcels 1 and 2, the northern portion of proposed Parcel 3 and the western portion of proposed Parcel 4 (see Figures 1 and 2).

Survey Area Environmental Setting

Most of Survey Area 1 was burned in the Thomas Fire (December 2017) extending to near residences along the eastern side of Floral Road (proposed Parcel 4). Survey Area 1 consisted of:

- Proposed Parcels 1 and 2: fallow farmland.
- Northern portion of Parcel 3: a west-facing slope.
- Western portion of proposed Parcel 4: slopes surrounding the City of Ventura water tank, the adjacent small ridge to the north, the ephemeral drainage and adjacent slopes to the north.

An ephemeral drainage drains much of proposed Parcel 4, with a watershed of about 40 acres. Stormwater from this drainage is conveyed by a buried culvert under the residences to the west. The existing City of Ventura water tank site (2.12 acres) is not included within proposed Parcel 4.

Surrounding Area Environmental Setting

Existing single-family residences (Norway Tract) are located to the north of proposed Parcels 1 and 2, and west of proposed Parcel 4. Fallow farmland is located to the south of proposed Parcels 1 and 2. Undeveloped open space is located to the north, south and east of proposed Parcel 4. Oil production and storage facilities are located approximately one mile to the south and southeast of proposed Parcels 1 and 2.

Survey Area 2 (SA2)

The 67.7-acre Survey Area 2 encompassed about 60 acres of the 82.92-acre property. The area of overlap with Survey Area 1 was not fully surveyed.

Location

Survey Area 2 is located in the Ventura River valley, just east and south of a single-family residential area between Norway Drive and Floral Drive, and approximately 0.3 miles east of the Ventura River. Proposed Parcel 1 is located adjacent to Ventura Avenue (see Figure 2).

Survey Area Boundaries

Survey Area 2 encompassed all of proposed Parcel 3 (including immediately adjacent portions of Manuel Canyon), and the eastern and northwestern portions of proposed Parcel 4, focusing on the ephemeral drainage and the eastern slopes (not included in Survey Area 1).

Survey Area Environmental Setting

Most of the Survey Area was burned in the Thomas Fire (December 2017) extending to near residences along the eastern side of Floral Road (proposed Parcel 4). Survey Area 2 consisted of:

- Entire Parcel 3: mostly a west-facing slope and a small portion of Manuel Canyon.
- Most of Parcel 4: composed of a small east-west oriented canyon with ephemeral drainage, and south-facing slopes near the water tank site.

The ephemeral drainage drains much of proposed Parcel 4, with a watershed of about 40 acres. Stormwater from this drainage is conveyed by a buried culvert under the residences to the west. The existing City of Ventura water tank site (2.12 acres) is not included within proposed Parcel 4.

Surrounding Area Environmental Setting

Existing single-family residences (Norway Tract) are located to the north of proposed Parcels 1 and 2, and west of proposed Parcel 4. Fallow farmland is located to the south of proposed Parcels 1 and 2. Undeveloped open space is located to the north, south and east of proposed Parcel 4. Oil production and storage facilities are located approximately one mile to the south and southeast of proposed Parcels 1 and 2.

Survey Area 3 (SA3)

Survey Area 3 encompassed about 10 acres of the 82.92-acre property, and included all areas supporting larger trees located within 200 feet of the grading limits (protected tree survey).

Location

Survey Area 3 is located in the Ventura River valley, just south of a single-family residential area between Norway Drive and Floral Drive, and approximately 0.3 miles east of the Ventura River. Proposed Parcel 1 is located adjacent to Ventura Avenue (see Figure 2).

Survey Area Boundaries

Survey Area 3 encompassed portions of proposed Parcels 1, 2 and 3.

Survey Area Environmental Setting

The eastern portion of Survey Area 3 was burned in the Thomas Fire (December 2017). Survey Area 3 consisted of:

- Western and northern portion of proposed Parcel 1.
- Northern portion of proposed Parcel 2.

- Northwestern portion of proposed Parcel 3.

Surrounding Area Environmental Setting

Existing single-family residences (Norway Tract) are located to the north of proposed Parcels 1 and 2, and west of proposed Parcel 4. Fallow farmland is located to the south of proposed Parcels 1 and 2. Undeveloped open space is located to the north, south and east of proposed Parcel 4. Oil production and storage facilities are located approximately one mile to the south and southeast of proposed Parcels 1 and 2.

Survey Area 4 (SA4)

Survey Area 4 encompassed approximately 30.2 acres of the 82.92-acre property and focused on suitable bumblebee habitat.

Location

Survey Area 4 is located in the Ventura River valley, just south of a single-family residential area between Norway Drive and Floral Drive, and approximately 0.3 miles east of the Ventura River. Proposed Parcel 1 is located adjacent to Ventura Avenue (see Figure 2).

Survey Area Boundaries

Survey Area 4 encompassed portions of proposed Parcels 3 and 4.

Survey Area Environmental Setting

Most of Survey Area 4 was burned in the Thomas Fire (December 2017). Survey Area 4 consisted of:

- The northern portion of proposed Parcel 3, including deerweed scrub, a plant community used by bumblebees.
- The southern portion of proposed Parcel 4, including purple sage scrub, a plant community used by bumblebees.

Surrounding Area Environmental Setting

Existing single-family residences (Norway Tract) are located to the west of proposed Parcel 4. Undeveloped open space is located to the north, south and east of proposed Parcel 4. Oil production and storage facilities are located approximately one mile to the south and southeast of proposed Parcels 1 and 2.

Protocol Surveys for Crotch's Bumblebee (*Bombus crotchii*)

Foraging surveys for Crotch's bumblebee were conducted in accordance the CDFW Survey Considerations for California Endangered Species Act (CESA) Candidate Bumble Bee Species protocol dated June 6, 2023. In total, three surveys were conducted within suitable habitat (Survey Area SA4) during the colony active period (April - August) for Crotch's bumblebee (CDFW 2023). Survey efforts focused on areas of accessible patches of flowering known bumblebee floral resources, including, but not limited to, deerweed (*Acmispon glaber*), purple sage (*Salvia leucophylla*), and branching phacelia (*Phacelia ramosissima*). Bumblebees were observed using 10x42 binoculars. When feasible, observed bumblebees were photographed in-situ.

Bumblebees which were not readily identifiable through observation with binoculars or in-situ photography, or which were of interest were captured in a sterile plastic or glass vile, placed in a cooler with crushed ice with a temperature between 30° F (-1.1° C) and 40° F (4.4° C), and held for at least 10 minutes, but not exceeding 30 minutes. Following the cooling period, the individual bumblebee(s) was removed, placed on a white sheet of paper, and photographed at multiple angles, with particular attention paid to photographing the face, cheek (malar) length, head/face hair color, anterior scutum and scutellum hair color, inner-alar space color, abdomen terga hair color, and basitarsus morphology. All photography was completed using a Canon 100mm F2.8 macro lens and a Canon R5 mirrorless camera. Following the capture period, the bumblebee individuals were released in a shaded area within 5 meters of the capture point. Photographic vouchers were uploaded to iNaturalist (https://www.inaturalist.org) and to the Bumble Bee Atlas (https://www.bumblebeewatch.org) under Mr. Abbey's personal account.

Section 3: The Biological Inventory

See Appendix One for an overview of the types of biological resources that are protected in Ventura County.

3.1 Ecological Communities: Plant Communities, Physical Features and Wetlands

Background Research

Each of the references listed in Section 2.3 were consulted to identify biological resources of concern.

Plant Communities

Locally important or rare plant communities were found within the survey area(s).

Major Plant Communities Summary

The following is a description of each major plant community, based on the vegetation classification of A Manual of California Vegetation (Sawyer et al., 2009). Figures 3 and 4 provide a map of plant communities within the survey areas.

PC1: Wild Oats and Annual Brome Grassland *(Avena* spp. - *Bromus* spp. Herbaceous Semi-Natural Alliance). This classification is used to describe areas disturbed by historic grazing and recent wildfire supporting mostly annual non-native grasses (mostly rip-gut grass [*Bromus diandrus*]) and herbs including scattered milk thistle (*Silybum marianum*) and summer mustard (*Hirschfeldia incana*).

PC2: California Brittle Bush Scrub (*Encelia californica - Eriogonum cinereum* Shrubland Alliance). This community occurs as two small patches is the southwestern portion of proposed Parcel 4 and is dominated by California brittle bush (*Encelia californica*). This plant community has been assigned a rarity ranking of S3 by NatureServe (vulnerable to extirpation in California).

PC3: Coast Live Oak Woodland (*Quercus agrifolia* Forest & Woodland Alliance). This community occurs on the north-facing slope in the southern portion of proposed Parcel 4 and is dominated by coast live oak (*Quercus agrifolia*). The understory of this woodland is variable, but includes purple nightshade (*Solanum xantii*), rip-gut grass, poison hemlock (*Conium maculatum*) and giant wild-rye (*Leymus condensatus)*. This plant community has been assigned a rarity ranking of S4 by NatureServe (apparently secure in California).

PC4: Coyote Brush Scrub (*Baccharis pilularis* Shrubland Alliance). This community occurs along the ephemeral drainage on proposed Parcel 4 and is dominated by coyote brush (*Baccharis pilularis*) with some giant wild-rye. This plant community has been assigned a rarity ranking of S5 by NatureServe (secure in California).

PC5: Deerweed Scrub (Deerweed - silver lupine - yerba santa scrub). This community occurs on proposed Parcel 3 and likely associated with post-fire recovery. It is dominated by deerweed (*Acmispon glaber*) with some purple sage (*Salvia leucophylla*) and lemonade berry (*Rhus integrifolia*). This plant community has been assigned a rarity ranking of S5 by NatureServe (secure in California).

PC6: Developed. This term is used to describe paved roads, the existing residence, water tank and associated disturbed areas and landscaping.

PC7: Disturbed. This term is used to describe the vegetation of the fallow farmlands on Parcels 1 and 2 and a graded area on proposed Parcel 4 (previously planned development area). Most of proposed Parcels 1 and 2 supported citrus orchards until June 2023. The vegetation of this area is currently dominated by prickly ox tongue (*Helminthotheca echioides*), sow thistle (*Sonchus oleraceus*), sour clover (*Melilotus indicus*) and Johnson grass (*Sorghum halepense*).

PC8: Foothill Needlegrass Grassland (*Nassella* spp. - *Melica* spp. Herbaceous Alliance). This community occurs as two small patches on the north-facing slope south of the ephemeral drainage on proposed Parcel 4 and is dominated by foothill needlegrass (*Stipa lepida*). This plant community has been assigned a rarity ranking of S3 by NatureServe (vulnerable to extirpation in California).

PC9: Giant Wild-Rye Grassland (*Leymus condensatus* Herbaceous Alliance). This community occurs as several patches on proposed Parcel 4 and is dominated by giant wild-rye, with scattered purple sage. This plant community has been assigned a rarity ranking of S3 by NatureServe (vulnerable to extirpation in California).

PC10: Lemonade Berry Scrub (*Rhus integrifolia* Shrubland Alliance). This community occurs in the northern portion of proposed Parcel 3 and adjacent areas of proposed Parcel 4 and is dominated by lemonade berry with lesser amounts of deer-weed, California brittle bush and purple sage. This plant community has been assigned a rarity ranking of S3 by NatureServe (vulnerable to extirpation in California).

PC11: Mulefat thickets (*Baccharis salicifolia* Shrubland Alliance). This community occurs as a linear strip along the ephemeral drainage on proposed Parcel 4 and is dominated by mulefat (*Baccharis salicifolia*). This plant community has been assigned a rarity ranking of S4 by NatureServe (apparently secure in California).

PC12: Orchards. This term is used to describe avocado orchards in the southwestern corner of proposed Parcel 4 and the eastern portion of Parcel 2.

PC13: Poison Hemlock Patches (Conium maculatum - Foeniculum vulgare Herbaceous Semi-Natural Alliance). This term is used to describe a patch of poison hemlock on a north-facing slope on proposed Parcel 4.

PC14: Poison Oak Scrub (*Toxicodendron diversilobum* Shrubland Alliance). This community mostly occurs on the north-facing slope in the western portion of proposed Parcel 4 and is dominated by poison oak (*Toxicodendron diversilobum*), with small patches of giant wild-rye and purple sage. This plant community has been assigned a rarity ranking of S4 by NatureServe (apparently secure in California).

PC15: Purple Sage Scrub (*Artemisia californica - Salvia leucophylla* Shrubland Alliance). This community occurs on the north-facing slope in the central portion of proposed Parcel 4 as well as the northwest-facing slope in the southeastern portion of proposed Parcel 4. Purple sage scrub is dominated by purple sage with scattered giant wild-rye and sawtooth golden bush (*Hazardia squarrosa*). This plant community has been assigned a rarity ranking of S5 by NatureServe (secure in California).

PC16: Sawtooth Golden Bush Scrub (*Hazardia squarrosa* Shrubland Alliance). This community occurs on the north-facing slope in the central portion of proposed Parcel 4 and is dominated by sawtooth golden bush and giant wild-rye. This plant community has been assigned a rarity ranking of S3 by NatureServe (vulnerable to extirpation in California).

PC17: Upland mustards (*Brassica nigra* - *Centaurea (solstitialis, melitensis*) Herbaceous Semi-Natural Alliance). This term is used to describe patches of black mustard (*Brassica nigra*) and summer mustard (*Hirschfeldia incana*), mostly located on proposed Parcel 4.

PC18: California Walnut Groves (*Juglans californica* Forest & Woodland Alliance). This community occurs on the north-facing slope in the southern portion of proposed Parcel 4 and along the boundary of proposed Parcels 2 and 3. California walnut groves are dominated by southern California black walnut (*Juglans californica*). This plant community has been assigned a rarity ranking of S3 by NatureServe (vulnerable to extirpation in California).

PC19: Eucalyptus Groves (Eucalyptus - tree of heaven - black locust groves). This term is used to describe small groves of planted blue gum (*Eucalyptus globulus*) and red iron-bark (*Eucalyptus sideroxylon*) on proposed Parcels 1 and 3.

Sensitive Plant Communities

Six sensitive plant communities (rarity ranking of S3, vulnerable to extirpation in California) occur within the survey areas, including California brittle bush scrub, foothill needlegrass grassland, sawtooth golden bush scrub, giant wild-rye grassland, lemonade berry scrub and California walnut groves (see Plant Communities Table). These plant communities are limited to the eastern margin of proposed Parcel 2 and proposed Parcels 3 and 4 and would not be affected by proposed development.

Vegetation data was collected and a Combined Vegetation Rapid Assessment and Releve Form was completed on April 23, 2024 within each of the six sensitive plant communities found within the survey area. The CDFW-CNPS Protocol for the Combined Vegetation Rapid Assessment and Releve Form (updated April 16, 2024) was followed to collect these data. These forms with photographs are provided as Attachment C. The location of the sample plot within each of the six sensitive plant communities is provided in Figures 1 and 2.

Physical Features

No potentially important physical features were found within the survey areas.

Waters and Wetlands

See Appendix One for an overview of the local, state and federal regulations protecting waters, wetlands and riparian habitats. Wetlands are complex systems; delineating their specific boundaries, functions and values generally takes a level of effort beyond the scope of an Initial Study Biological Assessment (ISBA). The goal of the ISBA with regard to waters and wetlands is simply to identify whether they may exist or not and to determine the potential for impacts to them from the proposed project. This much information can be adequate for designing projects to avoid impacts to waters and wetlands. Additional studies are generally warranted to delineate specific wetland boundaries and to develop recommendations for impact minimization or impact mitigation measures.

Protected wetlands or waters were found within the survey area(s).

Waters and Wetlands Summary

For the purposes of this ISBA, waters are defined as areas meeting the definition for waters, wetlands and streambeds used by the U.S. Army Corps of Engineers, California Department of Fish and Wildlife (CDFW), California Coastal Commission (Coastal Zone only) and Ventura County (red-line streams regulated by the Ventura County Watershed Protection District) (see definition on page 28 of the Initial Study Assessment Guidelines). In addition, waters of the State and wetlands regulated by the Regional Water Quality Control Board are considered waters for the purposes of this ISBA.

For the purposes of this ISBA, wetlands are defined as areas that support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions (see Ventura County 2040 General Plan glossary). Since potential wetlands located within the survey areas would not be affected by proposed development, a wetlands delineation was not conducted and wetlands mapped by the National Wetland Inventory (NWI) are assumed to meet the County's wetland definition. Limited wetland hydrology data (evidence of surface water, soil saturation, sediment deposits, drift deposits, drainage patterns) collected on June 5, 2024 at Wetland W1 and an interview with the adjacent property owner indicate the NWI mapping is relatively accurate in describing seasonally saturated soils (County wetlands). Therefore, NWI mapping is presented on the Wetlands Map (Figure 6) as County defined wetlands.

Wetland W1. This wetland occurs within the ephemeral drainage on proposed Parcel 4. Approximately 1,500 feet of the western portion of the ephemeral drainage on proposed Parcel 4 supports an identifiable streambed and banks and may be considered a jurisdictional streambed by CDFW and RWQCB. Vegetation found within the survey area requiring saturated or seasonally saturated soils is limited to approximately 0.12 acres of mulefat thickets along the ephemeral drainage. The National Wetlands Inventory indicates the ephemeral drainage supports wetlands, including 1.90 acres of palustrine, scrub-shrub, temporary flooded wetlands and 1.08 acres of palustrine, emergent, persistent temporary flooded wetlands. The upper reach of this drainage supported saturated soils and ponded water in late spring (June 5, 2024) indicating a spring may contribute surface water to this drainage.

Wetland W2. This wetland occurs within Manuel Canyon at the very southern extent of proposed Parcel 3. The Manuel Canyon drainage extends approximately 2.4 miles east from its confluence with the Ventura River at river mile 3.9. The lower 1.7 miles of the Manuel Canyon drainage is maintained by the Ventura County Watershed Protection District and is considered waters of the U.S., waters of the State and within CDFW jurisdiction. The National Wetlands Inventory indicates the Manuel Canyon drainage supports wetlands, including palustrine, scrub-shrub temporary flooded wetlands and palustrine forested/shrub wetland.

Waters and Wetlands

Map Key	Wetland Type	Wetland Name (if any)	Wetland Status (3) (if known)	Wetland Size (4)	Hydrologic Status (5)	Primary Water Source (6)
W1	Drainage, possible spring	Unnamed	County, CDFW, RWQCB	2.98 acres based on NWI mapping	Saturated, some ponding	Runoff, possible spring
W2	Drainage	Manuel Canyon	County, CDFW, USACE, WPD, RWQCB	About 1.7 miles, about 40 linear feet and 0.03 acres (CDFW) within proposed Parcel 3	Saturated	Runoff

USACE..... U.S. Army Corps of Engineers regulated
CDFW..... California Department of Fish & Wildlife regulated
County..... County General Plan protected wetland
WPD..... Co. Watershed Protection District (red-line stream)
RWQCB…….Regional Water Quality Control Board

Waters and Wetlands (continued)

Map Key	County Wetland Significance	Wetland Distance from Project	Comments
W1	Not significant	850 feet	Riparian vegetation (mulefat scrub) limited to a linear 0.12-acre area along a short reach of the drainage, wetland functions limited to minor groundwater recharge and flood control
W2	Significant	400 feet	Riparian vegetation limited, but these wetlands provide groundwater recharge, flood control, pollution filtration and wildlife habitat

Water/Wetland Buffers

General Plan Policy COS-1.11 requires a minimum 100-foot buffer from wetland habitats but allows adjustment of the buffer upon evaluation by a qualified biologist. Since proposed development would be located at least 400 feet from the nearest waters or wetlands, formal buffers are not required.

3.2 Species

Observed Species

A total of 129 vascular plant species were identified during botanical surveys conducted on May 2 and June 5, 2024 and observations during bumblebee surveys, within the survey areas (see Appendix 2-A). Sixty (47 percent) of these species are native to California, while 69 of these species (53 percent) are non-native species). Thirty-one (24 percent of the total plant species reported) are listed as invasive by the California Invasive Plant Council, including two species rated as highly invasive (red brome, English ivy), 14 species rated as moderately invasive, and 15 species considered to have limited invasiveness (see Appendix 2-A). Two special-status plant species (southern California black walnut and Plummer's baccharis) were observed within the survey areas.

A total of 54 vertebrate animal species were observed within the survey areas (see Appendix 2-B), including three reptile species, 44 bird species and seven mammal species. Nine special-status wildlife species (Cooper's hawk, Allen's hummingbird, Nuttall's woodpecker, wrentit, oak titmouse, yellow warbler, yellow-breasted chat, California thrasher, Bullock's oriole) were observed within the survey areas.

During the three protocol Crotch's bumblebee surveys conducted within suitable habitat (Survey Area SA4), no Crotch's bumblebee individuals were detected at any point. Potential bumblebee nest locations, in the form of mammalian burrows, were documented within SA4. However, no occupied bumblebee nests were documented during any of the surveys. Three bumblebee species (California bumblebee, yellow-faced bumblebee, black tail bumblebee) were observed during the Crotch's bumblebee protocol surveys.

Protected Trees

Trees protected under the County's Non-Coastal Zoning Ordinance Tree Protection Regulations include:

- Native oak trees with a girth of 9.5 inches or greater, or 6.5 inches if a multi-trunked tree.
- Southern California black walnut trees with a girth of 9.5 inches or greater.
- Heritage trees defined as any species of tree with a single trunk of 90 or more inches in girth, or trees with multiple trunks, two of which collectively measure 72 or more inches in girth. Trees with unnaturally large trunks such as date palms must be at least 60 feet tall or 75 years old to be considered a protected tree.

An Arborist Report (see Attachment D) was prepared by Cragoe Pest Services for the proposed project which identified and surveyed all protected trees within 200 feet of the grading limits of the proposed development (see Protected Trees Table below). Note that the Arborist Report provided only collective tree diameters (not individual trunks), which were converted to girth. The use of collective tree diameters is inconsistent with the Tree Protection Guidelines as it prevents the calculation of cross-sectional area of each trunk for tree replacement. The location of these protected trees is provided in Figure 2.

Protected Trees (Arborist Report)						
Tree no.	Species	Common Name	California Invasive Plant Council Invasiveness Rating	Collective Diameter at Breath Height (inches)	Collective Girth (inches)	Impact
640	*Cedrus deodara*	Deodar cedar		43	135	Removal
641	*Grevillea robusta*	Silk oak	Watch	59	185	Removal
642	*Cedrus deodara*	Deodar cedar		136	427	Removal
643	*Quercus agrifolia*	Coast live oak		5	16	Encroachment
644	*Quercus agrifolia*	Coast live oak		5.5	17	Encroachment

651	*Quercus agrifolia*	Coast live oak		17	53	No impact
652	*Quercus agrifolia*	Coast live oak		9	28	No impact
653	*Juglans californica*	California black walnut		39	123	No impact
654	*Quercus agrifolia*	Coast live oak		46.5	146	No impact
655	*Quercus agrifolia*	Coast live oak		21	66	No impact
656	*Quercus agrifolia*	Coast live oak		7.5	24	No impact
657	*Quercus agrifolia*	Coast live oak		18.5	58	No impact

Special-Status Species and Nests

See Appendix One for definitions of the types of special status species that have federal, state or local protection and for more information on the regulations that protect birds' nests.

Special-status species were observed or have a moderate to high potential to occur within the survey area(s).

Habitat suitable for nests of birds protected under the Migratory Bird Treaty Act does exist within the survey area(s).

Special-Status Species Summary

Species included in the special-status species table are those species reported by the California Natural Diversity Data Base within five miles of the survey areas, and those Ventura County locally important plant and animal species reported within the Ventura 7.5-minute quadrangle map.

Three special-status plant species (southern California black walnut, Plummer's baccharis and Fish's milkwort) and two protected native tree species (coast live oak and southern California black walnut) were observed within the survey areas (see Figures 3 and 4). Nine special-status wildlife species were observed within the survey areas; Cooper's hawk, Allen's hummingbird, Nuttall's woodpecker, wrentit, oak titmouse, yellow warbler, yellow-breasted chat, California thrasher, Bullock's oriole (see locations in Figures 3 and 4).

The Special-Status Species Table provides a summary of the potential for other special-status plant species (SSP1 through SSP35) known from the area to occur within the survey areas. The Special-Status Species Table also provides a summary of the potential for other special-status wildlife species (SSP36 through SSP55) known from the area to occur within the survey areas.

Critical habitat for the endangered willow flycatcher and endangered southern California steelhead is located in the Ventura River 0.2 miles west of the survey areas. Critical habitat for the threatened California red-legged frog is located 2.9 miles to the north-northwest of the survey areas. Critical habitat for the threatened western snowy plover is located 4.0 miles south of the survey areas.

Special-Status Species						
Map Key (1)	Survey/Source (2)	Scientific Name (3)	Common Name	Species' Status (4)	Potential to Occur (5)	Habitat Requirements (6)

LIS .....Ventura County Locally Important Species

Nesting Bird Summary

Nests of birds protected by the federal Migratory Bird Treaty Act may be present in the survey areas, primarily within native plant communities (PC2-PC5, PC8-PC11, PC14-PC16, PC18) and non-native tree stands (including PC19).

3.3 Wildlife Movement and Connectivity

Wildlife movement or connectivity features, or evidence thereof, were not found within the survey area(s).

Mapped Corridors or Linkages

The project site and survey areas are not located within a habitat connectivity and wildlife corridor (HCWC overlay) as identified by the Ventura County Planning Division and not located within one of 15 priority landscape linkages identified by the South Coast Missing Linkages Project.

Connectivity Features

There are no natural or manmade features that facilitate wildlife movement through the property. The survey areas are located along the western margin of a large habitat block of over 100 square miles including the coastal foothills and Sulfur Mountain, bordered by State Route (SR) 33 to the west and SR 150 to the north and east. Due to relatively low traffic volumes and vehicle speeds (mostly less than 50 mph), these roadways are not impassable barriers (such as a major freeway) to wildlife moving into and out of this habitat block. SR 33 near the project site is a partial barrier to wildlife movement.

The northern and western boundary of proposed Parcels 1 and 2 is fenced (barbed wire or masonry block wall). The western boundary and most of the northern, southern and eastern boundary of proposed Parcel 4 is fenced (about four feet high, barbed wire) which may form a partial barrier to large mammals (coyote, bobcat, young deer, wild pig and bears). The approximate location of fencing is provided in Figures 3 and 4. There are no features within the survey areas which may facilitate wildlife movement.

Section 4: Impact Assessment and Mitigation

4.1 Sufficiency of Biological Data

Biological data is sufficient for the purposes of the ISBA.

4.2 Impacts and Mitigation

Cumulative projects assessed in this section include projects listed in the July 8, 2024 Planning Division Pending Projects List and Recently Approved Projects List in the North Ventura Avenue and Ojai Valley planning areas.

A. Species Project: PS-M; Cumulative: PS-M

Listed Species

Based on field surveys and habitat assessment, endangered, threatened or rare species were not observed or anticipated to occur within the survey areas or project grading limits.

Non-listed Special-Status Species

Southern California black walnut, Plummer's baccharis and Fish's milkwort were observed within the survey areas during the field surveys (see Figures 3 and 4). These species do not occur within the proposed grading limits or fuel modification areas. The proposed development would not result in the loss of suitable habitat for these species, or other special-status plant species that have the potential to occur within the affected parcels (see Special-Status Species Table).

Cooper's hawk, Allen's hummingbird, Nuttall's woodpecker, wrentit, yellow warbler, yellow-breasted chat, California thrasher, Bullock's oriole and oak titmouse were observed within the survey areas. The proposed development would not result in the loss of suitable habitat for these species, or other special-status wildlife species that have the potential to occur within the affected parcels (see Special-Status Species Table).

Protected Trees

Implementation of the project would result in the removal of seven protected heritage trees (tree nos. 640, 641, 642, 645, 646, 647, 648). The proposed project would require a discretionary tree permit and may be approved under Section 8107-27.4(c) of the Non-Coastal Zoning Ordinance should the Planning Director determine that the public benefit of the project outweighs removal of the six protected trees (four of which are or suspected to be invasive plant species).

Significance Finding – Project Impacts: Potentially Significant but Mitigable.

Significance Finding – Cumulative Impacts: Potentially Significant but Mitigable.

MM-1: Protected Tree Protection and Replacement

Impact and Mitigation Goal: To protect and replace protected trees.

Mitigation Action and Timing: A tree protection plan shall be developed, approved and implemented according to the County's Content Requirements for Tree Protection Plans to protect trees during project construction. The Ventura County Tree Protection Guidelines require replacement of removed trees on a cross-sectional basis. Replacement trees shall be planted in compliance with the Tree Protection Guidelines as landscaping within the proposed development and on adjacent portions of Parcel 2 not supporting native vegetation. Tree species to be planted shall not be considered invasive by the California Invasive Plant Council. The tree protection plan and a tree planting and maintenance plan shall be submitted at least 60 days prior to the start of clearing and grubbing within the approved grading limits.

Monitoring: An arborist shall monitor the replacement trees within one week of planting and on an annual basis for five years after planting. A final report shall be prepared at the end of the five-year monitoring period.

Standards of Success: The replacement trees cumulatively exceed the cross-sectional trunk area of those protected trees removed.

Birds Protected Under the Migratory Bird Treaty Act and California Fish and Game Code

Potential impacts to nesting migratory birds protected by the Migratory Bird Treaty Act (MBTA) and the California Fish and Game Code may include take in the form of removal of active nests during vegetation clearing and grading activities.

Significance Finding – Project Impacts: Potentially Significant but Mitigable.

Significance Finding – Cumulative Impacts: Potentially Significant but Mitigable.

The following avoidance and minimization efforts have been proposed to offset potentially significant impacts associated with take of nesting migratory birds:

MM-2: Nest Avoidance

Impact and Mitigation Goal: To reduce take of nesting migratory birds.

Mitigation Action and Timing: Removal of vegetation shall be conducted in between August 16 and February 28th or 29th, during the fall and winter, after fledging and before the initiation of breeding activities.

Monitoring: No monitoring activities are suggested due to the proposed timing of clearing activities outside of the breeding bird period (generally defined as March 1 through August 15).

Standards of Success: No loss of nesting migratory birds.

MM-3: Breeding Bird Surveys

Impact and Mitigation Goal: To prevent take of nesting migratory birds.

Mitigation Action and Timing: If vegetation removal and/or heavy equipment usage must be conducted during the breeding bird nesting period (generally defined as March 1 through August 15), pre-construction breeding bird surveys shall be performed within vegetation removal and construction areas and within 200 feet of these areas to determine the location of bird nesting sites. If active nests are detected during the breeding season, nests shall be avoided during construction.

Monitoring: A breeding bird survey report shall be submitted to the County Planning Division, including measures to minimize impacts to active nests.

Standards of Success: If active nests are detected during the breeding season, nests shall be avoided during construction. To ensure adequate protection for breeding birds, buffers shall be maintained between active nests of nesting migratory birds and vegetation clearing and other heavy equipment activity. The size of the buffers shall be established in consultation with the California Department of Fish and Wildlife (CDFW) and/or United States Fish and Wildlife Service (USFWS).

B. Ecological Communities Project: NI; Cumulative: NI

Sensitive Plant Communities

Six sensitive plant communities (rarity ranking of S3, vulnerable to extirpation in California) occur within the survey areas, including California brittle bush scrub, foothill needlegrass grassland, sawtooth golden bush scrub, giant wild-rye grassland, lemonade berry scrub and California walnut groves (see Plant Communities Table). These plant communities are limited to the eastern margin of proposed Parcel 2 and proposed Parcels 3 and 4 and would not be affected by proposed development.

Significance Finding – Project Impacts: No Impact.

Significance Finding – Cumulative Impacts: No Impact.

Wetlands (W1 and W2, see Figure 6) as defined by Ventura County occur the survey areas. All development would be located at least 400 feet from these wetlands.

Significance Finding – Project Impacts: No Impact.

Significance Finding – Cumulative Impacts: No Impact.

C. Wildlife Movement and Connectivity Project: LS; Cumulative: LS

The project site and survey areas are not located within a habitat connectivity and wildlife corridor (HCWC overlay) as identified by the Ventura County Planning Division and not located within one of 15 priority landscape linkages identified by the South Coast Missing Linkages Project.

Habitat Loss within a Wildlife Movement Corridor

Native vegetation and habitat loss would be avoided and would not reduce cover and habitat for wildlife moving through the area.

Isolate Habitat within a Wildlife Movement Corridor

The proposed development would be located adjacent to existing residential development, Ventura Avenue and SR 33 and would not isolate wildlife habitat. The proposed preservation of Parcels 3 and 4 would permanently protect 53 acres of relatively undisturbed habitat within the regional habitat block formed by SR 33 to the west and SR 150 to the north and east.

Barriers to Wildlife Movement

The proposed project may include fencing along the eastern and southern boundaries to separate the development from adjacent agricultural lands. Such fencing would not be impassable to wildlife and would be located adjacent to existing residential and agricultural development and not isolate wildlife habitat. Spilt-rail fencing (or equivalent) is likely to be required as a condition of approval by the Ventura County Planning Division. Therefore, implementation of the proposed project would not result in barriers to wildlife movement.

Indirect Factors that May Hinder Wildlife Movement

The proposed project would be provided with exterior lighting for security purposes. It is anticipated that luminaires would be focused downward on adjacent multi-family structures. The proposed project would be located adjacent to existing residential development, agricultural lands and roadways and would not hinder wildlife movement or result in increased predation.

Project residents may keep small domestic animals (cats and dogs) in compliance with County regulations. However, animals that may disturb wildlife (such as dogs) would be contained within the residences at night (outdoor spaces are not provided for residents) when most wildlife movement occurs.

Proposed development would increase human presence at the project site. However, the project area currently supports residential development and the project-related increase in human presence would not significantly affect wildlife movement.

Significance Finding – Project Impacts: Less than Significant.

Significance Finding – Cumulative Impacts: Less than Significant.

Appendix One

Summary of Biological Resource Regulations

The Ventura County Planning Division, as “lead agency” under CEQA for issuing discretionary land use permits, uses the relationship of a potential environmental effect from a proposed project to an established regulatory standard to determine the significance of the potential environmental effect. This Appendix summarizes important biological resource regulations which are used by the Division’s biologists (consultants and staff) in making CEQA findings of significance:

Sensitive Status Species Regulations
Nesting Bird Regulations
Plant Community Regulations
Waters and Wetlands Regulations
Coastal Habitat Regulations
Wildlife Migration Regulations
Locally Important Species/Communities Regulations

Sensitive Status Species Regulations

Federally Protected Species

Ventura County is home to 29 federally listed endangered and threatened plant and wildlife species. The U.S. Fish and Wildlife Service (USFWS) regulates the protection of federally listed endangered and threatened plant and wildlife species.

FE (Federally Endangered): A species that is in danger of extinction throughout all or a significant portion of its range.

FT (Federally Threatened): A species that is likely to become endangered in the foreseeable future.

FC (Federal Candidate): A species for which USFWS has sufficient information on its biological status and threats to propose it as endangered or threatened under the Endangered Species Act (ESA), but for which development of a proposed listing regulation is precluded by other higher priority listing activities.

FSC (Federal Species of Concern): A species under consideration for listing, for which there is insufficient information to support listing at this time. These species may or may not be listed in the future, and many of these species were formerly recognized as "Category-2 Candidate” species.

The USFWS requires permits for the ‘taking’ of any federally listed endangered or threatened species. Take is defined by the USFWS as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct; may include significant habitat modification or degradation if it kills or injures wildlife by significantly impairing essential behavioral patterns including breeding, feeding, or sheltering.”

The Endangered Species Act (ESA) does not provide statutory protection for candidate species or species of concern, but USFWS encourages conservation efforts to protect these species. USFWS can set up voluntary Candidate Conservation Agreements and Assurances, which provide non-Federal landowners (public and private) with the assurance that if they implement various conservation activities to protect a given candidate species, they will not be subject to additional restrictions if the species becomes listed under the ESA.

State Protected Species

The California Department of Fish and Game (CDFG) regulates the protection of endangered, threatened, and fully protected species listed under the California Endangered Species Act. Some species may be jointly listed under the State and Federal Endangered Species Acts.

SE (California Endangered): A native species or subspecies which is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease.

ST (California Threatened): A native species or subspecies that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by this chapter. Any animal determined by the commission as "rare" on or before January 1, 1985, is a "threatened species."

SFP (California Fully Protected Species): This designation originated from the State's initial effort in the 1960's to identify and provide additional protection to those animals that were rare or faced possible extinction. Lists were created for fish, mammals, amphibians, reptiles, and birds. Most fully protected species have also been listed as threatened or endangered species under the more recent endangered species laws and regulations.

SR (California Rare): A species, subspecies, or variety of plant is rare under the Native Plant Protection Act when, although not presently threatened with extinction, it is in such small numbers throughout its range that it may become endangered if its present environment worsens. Animals are no longer listed as rare; all animals listed as rare before 1985 have been listed as threatened.

SSC (California Species of Special Concern): Animals that are not listed under the California Endangered Species Act, but which nonetheless 1) are declining at a rate that could result in listing, or 2) historically occurred in low numbers and known threats to their persistence currently exist.

The CDFG requires permits for the taking of any State-listed endangered, threatened, or fully protected species. Section 2080 of the Fish and Game Code prohibits "take" of any species that the California Fish and Game Commission determines to be endangered or threatened. Take is defined in Section 86 of the Fish and Game Code as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill."

The California Native Plant Protection Act protects endangered and rare plants of California. Section 1908, which regulates plants listed under this act, states: “no person shall import into this state, or take, possess, or sell within this state, except as incident to the possession or sale of the real property on which the plant is growing, any native plant, or any part or product thereof, that the commission determines to be an endangered native plant or rare native plant, except as otherwise provided in this chapter.”

The California Endangered Species Act does not provide statutory protection for California species of special concern, but they should be considered during the environmental review process.

California Native Plant Society Listed Species

Plants with CNPS listings 1A, 1B and 2 should always be addressed in CEQA documents. Plants with CNPS listings 3 and 4 do not explicitly qualify for legal protection, but can be addressed in CEQA documents depending on the circumstances and opinion of the biologist conducting the assessment.

CNPS 1A: Plants presumed to be extinct because they have not been seen or collected in the wild in California for many years. This list includes plants that are both presumed extinct in California, as well as those plants which are presumed extirpated in California. A plant is extinct in California if it no longer occurs in or outside of California. A plant that is extirpated from California has been eliminated from California, but may still occur elsewhere in its range.

CNPS 1B: Plants that are rare throughout their range with the majority of them endemic to California. Most of the plants of List 1B have declined significantly over the last century.

CNPS 2: Plants that are rare throughout their range in California, but are common beyond the boundaries of California. List 2 recognizes the importance of protecting the geographic range of widespread species.

Plants identified on CNPS Lists 1A, 1B, and 2 meet the definitions of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and are eligible for state listing. They should be fully considered during preparation of environmental documents relating to CEQA.

CNPS 3: A review list for plants for which there is inadequate information to assign them to one of the other lists or to reject them.

CNPS 4: A watch list for plants that are of limited distribution or infrequent throughout a broader area in California and their vulnerability or susceptibility to threat appears relatively low at this time.

Global and Subnational Rankings

Though not associated directly with legal protections, species have been given a conservation status rank by NatureServe, an international non-profit conservation organization that is the leading source for information about rare and endangered species and threatened ecosystems. The Ventura County Planning Division considers the following ranks as sensitive for the purposes of CEQA impact assessment (G = Global, S = Subnational or State):

G1 or S1 - Critically Imperiled
G2 or S2 – Imperiled
G3 or S3 - Vulnerable to extirpation or extinction

Locally Important Species

Locally important species' protections are addressed in a separate Appendix document, "Locally Important Species/Communities Regulations."

For lists of some of the species in Ventura County that are protected by the above regulations, go to www.ventura.org/rma/planning/bio_resources/index.htm.

Nesting Bird Regulations

The Federal Migratory Bird Treaty Act (MBTA) and the California Department of Fish and Game (CDFG) Code (3503, 3503.5, 3511, 3513 and 3800) protect most native birds. In addition, the federal and state endangered species acts protect some bird species listed as threatened or endangered. Project-related impacts to birds protected by these regulations would occur during the breeding season, because unlike adult birds, eggs and chicks are unable to escape impacts.

The MBTA implements various treaties and conventions between the U.S. and Canada, Japan, Mexico, and Russia for the protection of migratory birds, which occur in two of these countries over the course of one year. The Act maintains that it is unlawful to pursue, hunt, take, capture or kill; attempt to take, capture or kill; possess, offer to or sell, barter, purchase, deliver or cause to be shipped, exported, imported, transported, carried or received any migratory bird, part, nest, egg or product, manufactured or not. Bird species protected under the provisions of the MBTA are identified by the List of Migratory Birds (Title 50 of the Code of Federal Regulations, Section 10.13 as updated by the 1983 American Ornithologists' Union (AOU) Checklist and published supplements through 1995 by the USFWS).

CDFG Code 3513 upholds the MBTA by prohibiting any take or possession of birds that are designated by the MBTA as migratory nongame birds except as allowed by federal rules and regulations promulgated pursuant to the MBTA. In addition, there are CDFG Codes (3503, 3503.5, 3511, and 3800) which further protect nesting birds and their parts, including passerine birds, raptors, and state "fully protected" birds.

NOTE: These regulations protect almost all *native nesting birds*, not just sensitive status birds.

Plant Community Regulations

Plant communities are provided legal protection when they provide habitat for protected species, when the community is in the coastal zone and qualifies as environmentally sensitive habitat area (ESHA), or when the community qualifies as locally important.

Global and Subnational Rankings

Though not associated directly with legal protections, plant communities have been given a conservation status rank by NatureServe, an international non-profit conservation organization that is the leading source for information about rare and endangered species and threatened ecosystems. The Ventura County Planning Division considers the following ranks as sensitive for the purposes of CEQA impact assessment (G = Global, S = Subnational or State):

G1 or S1 - Critically Imperiled
G2 or S2 - Imperiled
G3 or S3 - Vulnerable to extirpation or extinction

CDFG Rare

Rare natural communities are those communities that are of highly limited distribution. These communities may or may not contain rare, threatened, or endangered species. Though the Native Plant Protection Act and the California Endangered Species Act provide no legal protection to plant communities, CDFG considers plant communities that are ranked G1-G3 or S1-S3 (as defined above) to be rare or sensitive, and therefore these plant communities should be addressed during CEQA review.

Environmentally Sensitive Habitat Areas

The Coastal Act specifically calls for protection of "environmentally sensitive habitat areas" or ESHA, which it defines as: "Any area in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and which could be easily disturbed or degraded by human activities and developments" (Section 30107.5).

ESHA has been specifically defined in the Santa Monica Mountains. For projects in this location, the Coastal Commission, the agency charged with administering the Coastal Act, has developed a specific three-part test for determining whether habitat there should be considered coastal sage scrub/chaparral ESHA. A memo from a Coastal Commission biologist outlining this test can be found at: www.ventura.org/rma/planning/pdf/bio_resources/ESHA_Santa_Monica_Mountains.pdf.

Locally Important Communities

The Ventura County Initial Study Assessment Guidelines defines a locally important community as one that is considered by qualified biologists to be a quality example characteristic of or unique to the County or region, with this determination being made on a case-by-case basis. The County has not developed a list of locally important communities, but has deemed oak woodlands to be a locally important community.

Waters and Wetlands Regulations

Numerous agencies control what can and cannot be done in or around streams and wetlands. If a project affects an area where water flows, ponds or is present even part of the year, it is likely to be regulated by one or more agencies. Many wetland or stream projects will require three main permits or approvals (in addition to CEQA compliance). These are:

- 404 Permit (U.S. Army Corps of Engineers)
- 401 Certification (Regional Water Quality Control Board)
- Streambed Alteration Agreement (California Department of Fish and Game)

In addition, the Ventura County General Plan calls for protection of wetlands and there are several other federal, state and local permits that could be required when a project involves disturbance to wetlands or waters. For a more thorough explanation of wetland permitting, see the Ventura County's "Wetland Project Permitting Guide" at www.ventura.org/rma/planning/pdf/prog_servs/bio_resources/FinalPDF.pdf.

404 Permit (U.S. Army Corps of Engineers)

Most projects that involve streams or wetlands will require a 404 Permit from the U.S. Army Corps of Engineers (USACE). Section 404 of the federal Clean Water Act is the primary federal program regulating activities in wetlands. The Act regulates areas defined as "waters of the United States." This includes streams, wetlands in or next to streams, areas influenced by tides, navigable waters, lakes, reservoirs and other impoundments. For nontidal waters, USACE jurisdiction extends up to what is referred to as the "ordinary high water mark" as well as to the landward limits of adjacent Corps-defined wetlands, if present. The ordinary high water mark is an identifiable natural line visible on the bank of a stream or water body that shows the upper limit of typical stream flow or water level. The mark is made from the action of water on the streambank over the course of years.

Permit Triggers: A USACE 404 Permit is triggered by moving (discharging) or placing materials—such as dirt, rock, geotextiles, concrete or culverts—into or within USACE jurisdictional areas. This type of activity is also referred to as a "discharge of dredged or fill material."

401 Certification (Regional Water Quality Control Board)

If your project requires a USACE 404 Permit, then you will also need a Regional Water Quality Control Board (RWQCB) 401 Certification. The federal Clean Water Act, in Section 401, specifies that states must certify that any activity subject to a permit issued by a federal agency, such as the USACE, meets all state water quality standards. In California, the state and regional water boards are responsible for certification of activities subject to USACE Section 404 Permits.

Permit Trigger: A RWQCB 401 Certification is triggered whenever a USACE 404 Permit is required, or whenever an activity could cause a discharge of dredged or fill material into waters of the U.S. or wetlands.

Streambed Alteration Agreement (California Department of Fish and Game)

If your project includes alteration of the bed, banks or channel of a stream, or the adjacent riparian vegetation, then you may need a Streambed Alteration Agreement from the California Department of Fish and Game (CDFG). The California Fish and Game Code, Sections 1600-1616, regulates activities that would alter the flow, bed, banks, channel or associated riparian areas of a river, stream or lake—all considered “waters of the state.” The law requires any person, state or local governmental agency or public utility to notify CDFG before beginning an activity that will substantially modify a river, stream or lake.

Permit Triggers: A Streambed Alteration Agreement (SAA) is triggered when a project involves altering a stream or disturbing riparian vegetation, including any of the following activities:

- Substantially obstructing or diverting the natural flow of a river, stream or lake
- Using any material from these areas
- Disposing of waste where it can move into these areas

Some projects that involve routine maintenance may qualify for long-term maintenance agreements from CDFG. Discuss this option with CDFG staff.

Ventura County General Plan

The Ventura County General Plan contains policies which also strongly protect wetland habitats.

Biological Resources Policy 1.5.2-3 states**:**

> Discretionary development that is proposed to be located within 300 feet of a marsh, small wash, intermittent lake, intermittent stream, spring, or perennial stream (as identified on the latest USGS 7½ minute quad map), shall be evaluated by a County approved biologist for potential impacts on wetland habitats. Discretionary development that would have a significant impact on significant wetland habitats shall be prohibited, unless mitigation measures are adopted that would reduce the impact to a less than significant level; or for lands designated "Urban" or "Existing Community", a statement of overriding considerations is adopted by the decision-making body.

Biological Resources Policy 1.5.2-4 states:

> Discretionary development shall be sited a minimum of 100 feet from significant wetland habitats to mitigate the potential impacts on said habitats. Buffer areas may be increased or decreased upon evaluation and recommendation by a qualified biologist and approval by the decision-making body. Factors to be used in determining adjustment of the 100 foot buffer include soil type, slope stability, drainage patterns, presence or absence of endangered, threatened or rare plants or animals, and compatibility of the proposed development with the wildlife use of the wetland habitat area. The requirement of a buffer (setback) shall not preclude the use of replacement as a mitigation when there is no other feasible alternative to allowing a permitted use, and if the replacement results in no net loss of wetland habitat. Such replacement shall be "in kind" (i.e. same type and acreage), and provide wetland habitat of comparable biological value. On-site replacement shall be preferred wherever possible. The replacement plan shall be developed in consultation with California Department of Fish and Game.

Coastal Habitat Regulations

Ventura County's Coastal Area Plan and the Coastal Zoning Ordinance, which constitute the "Local Coastal Program" (LCP) for the unincorporated portions of Ventura County's coastal zone, ensure that the County's land use plans, zoning ordinances, zoning maps, and implemented actions meet the requirements of, and implement the provisions and polices of California's 1976 Coastal Act at the local level.

Environmentally Sensitive Habitats

The Coastal Act specifically calls for protection of "environmentally sensitive habitat areas" or ESHA, which it defines as: "Any area in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and which could be easily disturbed or degraded by human activities and developments" (Section 30107.5).

Section 30240 of the Coastal Act states:

(a) "Environmentally sensitive habitat areas shall be protected against any significant disruption of habitat values, and only uses dependent on such resources shall be allowed within such areas."

(b) "Development in areas adjacent to environmentally sensitive habitat areas and parks and recreation areas shall be sited and designed to prevent impacts which would significantly degrade such areas, and shall be compatible with the continuance of such habitat areas."

There are three important elements to the definition of ESHA. First, a geographic area can be designated ESHA either because of the presence of individual species of plants or animals or because of the presence of a particular habitat. Second, in order for an area to be designated as ESHA, the species or habitat must be either rare or it must be especially valuable. Finally, the area must be easily disturbed or degraded by human activities.

Protection of ESHA is of particular concern in the southeastern part of Ventura County, where the coastal zone extends inland (~5 miles) to include an extensive area of the Santa Monica Mountains. The Coastal Commission, the agency charged with administering the Coastal Act, developed a specific three-part test for determining whether habitat in the Malibu area of the Santa Monica Mountains should be considered coastal sage scrub/chaparral ESHA. Given that Malibu is immediately adjacent to the Ventura County part of the Santa Monica Mountains, this three-part test can be used for assessing whether coastal sage scrub and chaparral habitat in the Ventura County coastal zone meets the definition of ESHA. A memo from a Coastal Commission biologist outlines this test and can be found at: www.ventura.org/rma/planning/pdf/bio_resources/ESHA_Santa_Monica_Mountains.pdf.

The County's Local Coastal Program outlines other specific protections to environmentally sensitive habitats in the Coastal Zone, such as to wetlands, riparian habitats and dunes. Protections in some cases are different for different segments of the coastal zone.

Copies of the Coastal Area Plan and the Coastal Zoning Ordinance can be found at: www.ventura.org/rma/planning/programs_services/local_coast/local_coast.htm.

Wildlife Migration Regulations

The Ventura County General Plan specifically includes wildlife migration corridors as an element of the region's significant biological resources. In addition, protecting habitat connectivity is critical to the success of special status species and other biological resource protections. Potential project impacts to wildlife migration are analyzed by biologists on a case-by-case basis. The issue involves both a macro-scale analysis—where routes used by large carnivores connecting very large core habitat areas may be impacted—as well as a micro-scale analysis—where a road or stream crossing may impact localized movement by many different animals.

Locally Important Species/Communities Regulations

Locally important species/communities are considered to be significant biological resources in the Ventura County General Plan, thus one of the County's threshold criteria for the evaluation of impacts to biological resources is whether the project impacts locally important species/communities.

Locally Important Species

The following criteria were developed with the assistance of local biologists:

Locally Important Animal Species Criteria

1. Taxa for whom habitat in Ventura County is crucial for their existence either globally or in Ventura County. This includes taxa for whom:
    - Populations in Ventura County represents 10% or more of the known extant global distribution; or
    - In Ventura County, there are less than 6 element occurrences, or less than 1,000 individuals, or less than 2,000 acres.
2. Native taxa that are generally declining throughout their range and/or are in danger of extirpation in Ventura County.

Locally Important Plant Species Criteria

A locally important plant is a taxon that is declining throughout the extent of its range AND has a maximum of five (5) element occurrences in Ventura County.

Locally Important Animal and Plant Species Criteria

In some cases, to be determined on an individual basis, there are taxa whose population(s) do not qualify as locally important species; however, certain locations where a taxon occurs will be defined as locally important. This includes:

- If known, the published type locality for a holotype specimen.
- The edge of a taxon's range. This criteria does not apply to non-native taxa or those taxa whose range and population(s) size is expanding.

The County maintains a list of locally important species, which can be found on the Planning Division website at: www.ventura.org/rma/planning/programs_services/bio_resources/bio_resources.htm. *This list should not be considered comprehensive.* Any species that meets the criteria qualifies as locally important, whether or not it is included on this list.

Locally Important Communities

The Ventura County Initial Study Assessment Guidelines defines a locally important community as one that is considered by qualified biologists to be a quality example characteristic of or unique to the County or region, with this determination being made on a case-by-case basis. The County has not developed a list of locally important communities. Oak woodlands have however been deemed by the Ventura County Board of Supervisors to be a locally important community.

The state passed legislation in 2001, the Oak Woodland Conservation Act, to emphasize that oak woodlands are a vital and threatened statewide resource. In response, the County of Ventura prepared and adopted an Oak Woodland Management Plan that recommended, among other things, amending the County's Initial Study Assessment Guidelines to include an explicit reference to oak woodlands as part of its definition of locally important communities. The Board of Supervisors approved this management plan and its recommendations.

Appendix 2A

Vascular Plants Observed at Ventura Ranch, Ventura County, California

Scientific Name	Common Name	Habit	Family	Wetland Status	Invasiveness Rating
Achillea millefolium	Yarrow	PH	Asteraceae	FACU	
Acmispon glaber var. glaber	Deerweed, California broom	PH	Fabaceae	*

Appendix 2A

Vascular Plants Observed at Ventura Ranch, Ventura County, California

Scientific Name	Common Name	Habit	Family	Wetland Status	Invasiveness Rating

Notes:
Scientific nomenclature follows The Jepson Manual Second Edition (Baldwin et al., 2012), including supplements (old names in brackets).
An "*" indicates non-native species which have become naturalized or persist without cultivation.
An "**" indicates species which have been planted and may not persist without cultivation.

Habit Definitions:
- AF = annual fern or fern ally.
- AG = annual grass.
- AH = annual herb.
- BH = biennial herb.
- PF = perennial fern or fern ally.
- PG = perennial grass.
- PH = perennial herb.
- PV = perennial vine.
- S = shrub.
- T = tree.

Invasiveness Rating from the online database of the California Invasive Plant Council

Wetland Status from Arid West 2022 Regional Wetland Plant List
- OBL - Obligate wetland: almost always occurs in wetlands (>99% probability)
- FACW - Facultative-Wetland: usually occurs in wetlands (67-99% probability)
- FAC - Facultative: equally likely to occur in wetlands or non-wetlands (34-66% probability)
- FACU - Facultative-Upland: usually occurs in non-wetlands (1-33% probability)
- UPL - Upland: almost always occurs in non-wetlands (>99% probability)
- *: not addressed in the wetland plant list, non-wetland species

SURVEYOR'S NOTES:

HORZ. DATUM: NAD83(2011), 2010.00 EPOCH – PER NGS OPUS
VERT. DATUM: NAVD88 – PER TIE TO LOCAL VCS BENCH MARK
PROJECTION: CALIFORNIA STATE PLANE COORDINATE SYSTEM, NAD83 (CCS83) – ZONE 5
BENCH MARK: VENTURA COUNTY BM "87-4 1971" (VCPID: 824) ELEV = 193.23' (NAVD88) – 1992 NGS ADJUSTMENT

BASIS OF BEARINGS: GRID – BASED ON CCS83 PROJECTION

ALL UNITS ARE U.S. SURVEY FEET.

BENCHMARK LOCATION:
4.15 MILE NORTHERLY ALONG VENTURA AVENUE FROM 17'S JUNCTION WITH THE S.P.R.R. (NEAR THE VENTURA COUNTY FAIRGROUNDS), BETWEEN THE JUNCTION OF NORWAY DRIVE AND THE HIGHWAY 33 OVERPASS, 127.0 FEET SOUTHEASTERLY FROM THE CENTER OF THE NORTHBOUND OVERPASS OF THE HIGHWAY, 121.0 FEET NORTHWESTERLY FROM THE EXTENDED CENTER OF NORWAY DRIVE, 35.0 FEET SOUTHEASTERLY FROM THE CENTER OF VENTURA AVENUE, 32.7 FEET SOUTHEASTERLY OF POWER POLE NO X13010E, 9.5 FEET NORTHEASTERLY OF A 6.0 FT. CHAIN LINK FENCE, IN THE CENTER OF A 48IN CATCH BASIN.

BOUNDARY LINES SHOWN HEREON ARE APPROXIMATE ONLY – DERIVED FROM AVAILABLE RECORD SURVEY MAPS / DATA AND DO NOT REPRESENT A COMPLETE BOUNDARY SURVEY. SIMILARLY, THE LOCATION OF THE VENTURA AVENUE CENTER LINE AND RIGHT-OF-WAY LINES SHOWN ON THIS MAP ARE ALSO APPROXIMATE.

REGISTERED PROFESSIONAL ENGINEER ROBERT R. HARLEY No. C 90478 CIVIL STATE OF CALIFORNIA

PROPOSED EASEMENTS

(PE1) PROPOSED VARIABLE WIDTH ACCESS EASEMENT TO THE GENERAL PUBLIC FOR PEDESTRIAN/VEHICULAR INGRESS AND EGRESS, AND TO ALL GOVERNMENTAL AGENCIES PROVIDING FOR THE PUBLIC HEALTH, SAFETY, AND WELFARE, TO BE RECORDED BY SEPARATE DOCUMENT.

(PE2) PROPOSED VARIABLE WIDTH ACCESS AND UTILITY EASEMENT FOR THE BENEFIT OF PARCELS 1 AND 2, TO BE RECORDED BY SEPARATE DOCUMENT.

(PE3) PROPOSED VARIABLE WIDTH ACCESS AND UTILITY EASEMENT FOR THE BENEFIT OF PARCEL 3, TO BE RECORDED BY SEPARATE DOCUMENT.

(PE4) PROPOSED 30' WIDE ACCESS EASEMENT FOR THE BENEFIT OF PARCEL 4 TO BE RECORDED BY SEPARATE DOCUMENT.

(PE5) PROPOSED EASEMENT FOR ADDITIONAL BRUSH CLEARANCE MODIFICATION ZONE PER VCFD STANDARDS.

(PE6) IRREVOCABLE OFFER TO DEDICATE AN EASEMENT TO THE COUNTY OF VENTURA FOR ROAD PURPOSES.

REVISION	DATE

Arborist Report

I. Introduction

Trees in Ventura County are governed by the Ventura County Tree Protection Ordinance (VCTPO). Many species of which are protected by this law to elevate the quality of life in the County. As such, when work involving protected species requires a permit, a report is needed to ensure the safety of the trees by setting up parameters by which the work is to be done.

The property owners have proposed to build a new project called Ventura Ranch Farmworker Housing. The project will affect some of the trees in the path of construction. Of the 18 protected trees in the immediate vicinity of the proposed improvements, 8 are considered Heritage trees due to their size (at least 90" circumference or, for multi-trunked, 2 limbs with a combined 72" circumference). Six trees will need to be removed and one tree relocated for the project to take place, five of the removals are heritage trees. Four others will have their Tree Protection Zones encroached upon for the construction to take place.

The County has adopted Tree Protection Regulations as specified in Section 8107-25.7 of the Code of Ordinances which states that if the construction requires a County-defined "heritage" tree to be felled, or when construction work involves removal, alteration or encroachment into the tree protection zone of 6 or more protected trees or four or more oaks or sycamores, a Discretionary Tree Permit is to be filed. Due to the need to remove five protected heritage trees and encroach into the protected zones (TPZ) of four other protected trees (3 oaks and 1 heritage eucalyptus), a Discretionary Tree Permit will be required for this project. This type of permit requires an Arborist Report be submitted by a qualified arborist to provide a technical evaluation of the trees involved.

David Cragoe, ISA Certified Arborist #WE-7161A, has been hired to provide an Arborist Report to address the requirements of the permit. His contact information can be found on the title page of this report.

II. Background

The new housing project will take place on the entirety of the level portion of the property. Most of the construction will be done on vacant land. An existing house and outbuildings will need to be removed for the project to take place. Most of the proposed roads, parking lots, and housing are situated on land that has no major trees or improvements. Care has been taken to locate the buildings as to cause the least disruption to the natural surroundings. Consequently, five non-native protected trees and one native protected tree are slated for removal. One protected native tree is to be transplanted elsewhere one the property. The activity will require that many of the remaining protected trees be guarded from the potentially harmful effects of the construction.

III. Site Observations

The lot is generally flat, with a large field in the center taking up the majority of the property. Trees line the fringes of the lot on the west and east, with one protected tree on the northern border. The trees on the east side are on a gentle slope amongst a small grove of avocado trees. The west side trees line N Ventura Ave. Many of the large, mature trees are approximately 75-100 years old, thus making them Heritage trees. One is adjacent to the existing house (Tree #646 on the plan),

indicating the age of the building as it was likely planted around the time of the original construction.

The most abundant protected tree is the Coast Live Oak, *Quercus agrifolia*, 11 of which are included in this report. There are a few mature specimens around the avocado orchard, but most are young and appear to be volunteers. A small group of lemon trees is located around the yard for the existing house. Most of the field is covered with a grassy crop that seems to not be in production at this time.

One common defect noted throughout the property's trees is that most of them have buried trunks. That is, either debris, mulch or soil has accumulated or been placed at the trunks to the extent that the root flare is buried and no longer visible. This condition will most certainly have a deleterious effect on the trees if not corrected.

All the protected trees have been numbered and field tagged with the tag located on the north side of each tree at breast height. The numbering begins on the southwestern side of the property and proceeds generally clockwise around the site.

IV. Tree Condition and Impact Tables

The tables on the following pages include all the protected trees located within the construction zone. They help determine the relative health of the trees and what qualifies them as protected or not based on their species and measurements. The dripline measurements page covers the trees from the spreadsheet of the previous page. The Individual Tree Analysis in the subsequent section will deal with the protected trees and the impact the new construction will have on them.

V. Individual Tree Analysis

Trees reviewed here are only the protected trees, as defined by the Ventura County Tree Protection Regulations, within the construction zone of the project. Please refer to the map on Appendix A for tree locations and the construction plan on Appendix B for tree locations with driplines and Tree Protection Zones (TPZs) as they interact with proposed plans. Trees are marked on the map and plan by their tree numbers. Photos of the trees are found in the following pages in Appendix C and may be referenced in the descriptions below. Due to the dense, crowded conditions in some areas, it may be difficult to tell which tree is being featured in a few of the photos as it was not possible to separate the tree from its neighbors.

Tree #640 [Heritage] (Deodar Cedar—*Cedrus deodara*) is one of the larger trees included in this report. Its single trunk has a 43" diameter at breast height (DBH) and stands at 59' high with a slightly larger canopy spread of 60'. It is located at the entrance to the property at the southwestern corner along N Ventura Ave. The trunk and major branches are obscured by Algerian ivy, which also grows down out of the low-branched canopy (ivy was cut for measurement clearance, but not removed from canopy or base of the trunk). The shape of this tree has been artificially sculpted by powerline clearance.

This tree is slated for removal due to construction of the south side of the driveway for the new southwest entry. No protection measures are needed.

Tree #641 [Heritage] (Silk Oak—*Grevillea robusta*) is a large double-trunked tree sitting on the western property line border just north of Tree #640. It is 31.5 feet high with a 49 foot canopy spread and a collective DBH of 59 inches. It is in crowded conditions, flanked by Deodar cedars. The trunk is buried with soil and debris and Algerian ivy is growing up the trunk and into the canopy. Weak crotches and low branches are observed. This tree is also artificially shaped by powerline clearance.

This tree is slated for removal due to construction of the north side of the driveway for the new southwest entry. No protection measures are needed.

Trees #642 [Heritage] (Deodar Cedar—*Cedrus deodara*) has six trunks comprising a 136" DBH, the largest of all trees in this report. It is the second-tallest tree at a height of 60.5' and ties for widest spread with Tree #640 at 60'. It is located north of Tree #641 along the western property line. This crowded tree has low branches (some of the branches are so low they appeared to be roots covered with ivy), deadwood, and Algerian ivy growing up its buried trunk and into the canopy. Like the previous two trees, this tree has been artificially sculpted by powerline clearance.

This tree is slated for removal due to construction plans for a walkway at the southwest entry. No protection measures are needed.

Tree #643 [Protected] (Coast Live Oak—*Quercus agrifolia*) is a relatively young, double-trunked tree with a combined 5" DBH and extremely crowded by Tree #642. It stands 20' tall with a 13.5' canopy spread. This tree displays low branches, twig-branch dieback, sparse foliage, deadwood,

and a buried trunk. As with most other trees, structural pruning, deadwooding, and removal of basal soil are recommended for this tree.

There will be a 13.5’ encroachment into the northwest side of the TPZ for the construction to take place since the tree sits so close to the proposed walkway, which will be about 1.5’ from the trunk. Hand-digging is necessary in this area as root disturbance is anticipated. Compaction may be an issue as well. Protective fencing should be placed to the extent possible.

Tree #644 [Protected] (Coast Live Oak—*Quercus agrifolia*) is another small oak, single-trunked, with a 5.5” DBH, standing 14’ in height with a spread of 15’. It is located along the western fence line, north of Tree #643. This tree has numerous concerns of which include crowding, low branches, weak crotches, twig-branch dieback, and sparse foliage. There is a dead tree resting on top of this tree, which is a contributing cause to the tree’s severe leaning posture. This tree would benefit from deadwooding, removing basal soil, and structural pruning.

This tree’s trunk will be 5’ east of the proposed walkway and the TPZ encroached upon by 10’ on the northwest side. Protected fencing is needed to the extent possible and work within the TPZ will need to be hand-dug.

Tree #645 [Protected] (Coast Live Oak—*Quercus agrifolia*) is a double-trunked tree. It stands just outside the property’s western fence, down the embankment from N Ventura Ave. It is the largest oak in this area at 13” in diameter and 26’ in height with a 20.5’ canopy. The chain-link fence has become partially embedded into the trunk, which is buried and has Algerian ivy growing up it and into the low-branched canopy. There are several branches entangled in barbed wire at the top of the fence. This tree is crowded by a row of Eucalyptus trees inside the fence to the east. To improve the health and appearance of this tree, structural pruning, deadwooding, and removal of basal soil and debris are recommended mitigations.

This tree is slated for removal due to construction plans for a walkway at the southwest entry. No protection measures are needed.

Tree #646 [Heritage] (Deodar Cedar—*Cedrus deodara*) is a large, triple-trunked tree with an 89” DBH, height of 56’, and a canopy spread of 56’. It sits within a fenced yard of an existing house at the southwestern corner of the property. There is a 3’ western branch stump which has termite galleries and should have been trimmed closer to the trunk. The tree would benefit from being structurally pruned and deadwooded.

This tree is slated for removal as it is in the center of the plans for the southwestern-most housing unit. No protection measures are needed.

Tree #647 [Protected] (Coast Live Oak—*Quercus agrifolia*), a double-trunked tree with a DBH of 4.5” and an equal spread and height of 11’, is the smallest tree included in this report. It is located along the western property line and is crowded by Eucalyptus trees to the west. There is a Eucalyptus branch resting on top of the tree and sparse foliage in the canopy.

Since this tree will be in the way of the water retention basin along the street on the west, it will require removal and is a good candidate for relocation due to its small stature, its final destination is yet to be determined.

Tree #648 [Heritage] (California [Peruvian] Pepper—*Schinus molle*) stands at 51' tall with a canopy spread of 47' and a 36" DBH. This low-branched tree is crowded by a row of Eucalyptus trees, which run along the western fence line. Well equipment on the north side of the tree is leaking water, likely contributing to the overall good health of the tree, however constant moisture could provide an optimal environment for growth of fungal disease. Recommended mitigations include structural pruning, deadwooding, and removing basal soil.

This tree is slated for removal as it is in the center of the proposed roadway near the northwestern entry. No protection measures are needed.

Tree #649 [Heritage] (Blue Gum Eucalyptus—*Eucalyptus globulus*) is the tallest tree in this report, standing at a height of 71'. It has a collective DBH of 50" between two trunks and a canopy spread measuring 34'. It is located within the fence in the northwestern corner of the property with Norway Dr to the north. There is evidence of tortoise beetle activity and a heavy blue gum galling wasp infestation. There are low branches and lots of hung-up bark shed strips stuck in the tree, especially in the narrow crotches. To improve the appearance and health of the tree, it is recommended the tree receive structural pruning, deadwooding, insect treatment, and removal of basal soil.

There is a property line on the northwest edge of the canopy that penetrates the TPZ by 2.5'. Any fencing or wall to be built on this side of the tree will require hand-digging within the TPZ and protective fencing, which may be moved during work and replaced once work concludes.

Tree #650 [Protected] (Coast Live Oak—*Quercus agrifolia*) is situated on the northern border wall of the property. It is a small, double-trunked tree standing at 16.5' high with a 13.5' canopy spread and a 7" DBH. Crowding bougainvillea grows along the border, which is 5' north of the buried trunk. The tree would benefit from structural pruning and removal of bougainvillea branches along with basal soil and debris.

This tree is flanked by the property line to the north and the proposed parking lot to the south, coming within 7.5' of the trunk at the edge of the dripline. The TPZ will also be encroached upon to the south by 7.5'. Protective fencing is required to the extent possible and any work within the TPZ will need to be hand-dug.

Tree #651 [Protected] (Coast Live Oak—*Quercus agrifolia*) is located on the eastern border of the property at the base of the slope at the north end of a small avocado grove, 15' east of the dirt road. It is 33' tall with a spread of 34' and a 17" DBH. The tree displays weak crotches, sparse foliage, and ants streaming up the trunk, which indicates homopterous pests in the canopy. Recommended interventions include structural pruning, deadwooding, removal of basal soil, and insect treatment.

No encroachment for this tree is anticipated, however protective fencing should be installed to the extent of the TPZ.

Tree #652 [Protected] (Coast Live Oak—*Quercus agrifolia*) is a single-trunked westward-leaning oak with a 9" DBH, a 33' height and a dripline 18' across. It is located on the slope in the avocado grove on the eastern border of the property. The tree displays weak crotches and narrow, columnar growth. Considerations for this tree include structural pruning and basal soil removal.

No harm from construction should come to this tree due to the requisite fencing.

Tree #653 [Heritage] (California Black Walnut—*Juglans californica*) stands on the slope in the avocado grove on the eastern property border. It is 52' tall with a collective 39" DBH from two trunks and a 56.5' spread. This low-branched canopy displays multiple bird nests with no foliage due to the season. The base of the trunk is damaged with a burn scar on the south side and trunk cavities on the north and south sides, suckers cropping up from the base. Mitigations recommended for the tree include structural pruning, deadwooding, and removing basal soil.

No encroachment of the protective fencing should be necessary.

Tree #654 [Heritage, Protected] (Coast Live Oak—*Quercus agrifolia*) is a triple-trunked tree located on the slope in the eastern avocado grove. It is the largest Coast Live Oak on the property with a combined DBH of 46.5", height of 54', and 39.5' canopy spread, qualifying it as both protected by species and heritage by size. The western side of the tree displays an exposed root and a wound on the southern trunk at 2 feet. Borers are present on the trunk. Structural pruning, deadwooding, insect treatment, and basal soil removal are recommended interventions.

No problems anticipated with protective fencing in place.

Tree #655 [Protected] (Coast Live Oak—*Quercus agrifolia*) is located just southeast of Tree #654 on the avocado grove slope. It has a 21" DBH, 47' height, and dripline width of 39.5'. There is a large wound on the west side of the trunk where a weak crotch failed, peeling down the bark. Suckers at the base should be allowed to grow to provide shade for the trunk. Twig-branch dieback is noted in the canopy. It is recommended that the tree receives structural pruning, deadwooding, and removal of basal soil.

Construction interference is not anticipated due to its location, however, fencing is required.

Tree #656 [Protected] (Coast Live Oak—*Quercus agrifolia*) has a 7.5" DBH, 25' height, and 19.5' canopy spread. It is located on the slope in the avocado grove, east of Tree #655 with which it is crowded. The double trunk displays streams of ants, scars (likely from fire) on the north side from 0-6 feet, and unusual scaling. Weak crotches are observed as well. Structural pruning and removing basal soil and debris are recommended for the health and appearance of the tree.

The TPZ will have to be fenced but there should be no need to encroach during the project.

Tree #657 [Protected] (Coast Live Oak—*Quercus agrifolia*) is a quintuple-trunked tree, standing 24' in height with an 18.5" DBH and a 23' spread. It appears to be two trees that have fused together, which is difficult to determine as the trunk is buried. There are possible fire scars on the north trunks, which are mostly healed over. This tree is crowded on the slope by an avocado tree to the west. Weak crotches are observed along trunks. Interventions recommended include structural pruning, deadwooding, and removal of basal soil.

Being high on the slope away from construction, there should be no significant issues to be concerned about. TPZ fencing required.

VI. Discussion

Several of the oaks and heritage trees are quite close to the disturbance areas, the buildings themselves, and the access roads. Due to the restrictions of the construction plans, options for alternate locations for proposed improvements are limited. As a result, six trees are being removed and one transplanted to make room for the development.

VII. Appraisals

Since this report is for a discretionary permit project, it requires the appraisal of the heritage and protected trees that will be removed for mitigation or offset purposes. The appraisals herein have been done using the *Guide for Plant Appraisal*, 9th edition put out by the Council of Tree and Landscape Appraisers, and its companion volume, *Species Classification and Group Assignment*, a publication of the Western Chapter of the International Society of Arboriculture.

There are six trees that are slated for removal, Trees #640, #641, #642, #645, #646 and #648. Five of the trees are non-native trees and have Heritage status due to their size: Deodar Cedar (*Cedrus deodara*) – 3, Silk Oak (*Grevillea robusta*) – 1, and California [Peruvian] Pepper (Sc*hinus molle*) – 1. Tree #645 is the only non-Heritage, native, protected tree slated for removal: Coast Live Oak (*Quercus agrifolia*) – 1.

There are various methods of obtaining tree valuations. For the purposes of this report, we will be using the Trunk Formula Method due to the fact that the trees are too large to be replaced by nursery stock. The Trunk Formula Method is as follows: The tree species, condition, location and size of trunk are compared with the cost of a nursery-available tree and then size-adjusted. Trunk sizes are adjusted downward for exceptionally large trees using the table on page 40 of the *Guide for Plant Appraisal*.

Tree #640 is a Deodar Cedar (*Cedrus deodara*), with a condition rating of 70% as the tree is encumbered by Algerian ivy and adjacent power lines. It has a trunk circumference of 135" from one trunk comprising a 43" diameter. It has a location rating of 70% and a species rating of 40%. The adjusted appraised trunk area is 1,273 in^2 less the replacement tree size of 33.17 in^2 equals 1,240 in^2. The Basic Tree Cost is 1,240 in^2 x the Unit Tree Cost of \$45/in^2 + the Installed Tree Cost of \$1,492.65 which equals \$57,293. The final **Appraised Value is \$11,200** or the Basic Tree Cost of \$57,293 x the Species rating of 40% x the Condition rating of 70% x the Location rating of 70%.

Tree #641 is a Silk Oak (*Grevillea robusta*), with a condition rating of 70% as the tree is crowded between two large cedar trees and adjacent power lines. It has a trunk circumference of 185" from two trunks comprising a 59" diameter. It has a location rating of 70% and a species rating of 30%. The adjusted appraised trunk area is 1,366 in^2 (531 in^2 from the 26" trunk and 835 in^2 from the 33" trunk) less the replacement tree size of 17.71 in^2 equals 1,348 in^2. The Basic Tree Cost is 1,348 in^2 x the Unit Tree Cost of \$84/in^2 + the Installed Tree Cost of \$1,487.64 which equals \$114,720. The final **Appraised Value is \$16,900** or the Basic Tree Cost of \$114,720 x the Species rating of 30% x the Condition rating of 70% x the Location rating of 70%.

Tree #642 is a Deodar Cedar (*Cedrus deodara*), with a condition rating of 75% as the tree is has many low trunks, some resting on the ground, and power line competition. It has a trunk circumference of 427" from six trunks comprising an 136" diameter. It has a location rating of 70% and a species rating of 40%. The adjusted appraised trunk area is 2,719 in^2 (1,149 in^2 from the 40" trunk, 707 in^2 from the 30" trunk, 254 in^2 from each of the two 18" trunks, 201 in^2 from the 16" trunk, and 154 in^2 from the 14" trunk) less the replacement tree size of 33.17 in^2 equals 2,686 in^2. The Basic Tree Cost is 2,686 in^2 x the Unit Tree Cost of \$45/in^2 + the Installed Tree Cost of \$1,492.65 which equals \$122,363. The final **Appraised Value is \$25,700** or the Basic Tree Cost of \$122,363 x the Species rating of 40% x the Condition rating of 75% x the Location rating of 70%.

Tree #645 is a Coast Live Oak (*Quercus agrifolia*), with a condition rating of 65% due to its encumbrance with the fence and proximity to powerlines. It has a trunk circumference of 41" from two trunks comprising a 13" diameter. It has a location rating of 70% and a species rating of 90%. The appraised trunk area is 86 in^2 (79 in^2 from the 10" trunk and 7 in^2 from the 3" trunk) less the replacement tree size of 23.75 in^2 equals 62.25 in^2. The Basic Tree Cost is 62.25 in^2 x the Unit Tree Cost of \$62/in^2 + the Installed Tree Cost of \$1,472.50 which equals \$5,332. The final **Appraised Value is \$2,180** or the Basic Tree Cost of \$5,332 x the Species rating of 90% x the Condition rating of 65% x the Location rating of 70%.

Tree #646 is a Deodar Cedar (*Cedrus deodara*), with a condition rating of 90% as the tree is in fairly good health. It has a trunk circumference of 279.5" from three trunks comprising an 89" diameter. It has a location rating of 80% and a species rating of 40%. The appraised trunk area is 2,073 in^2 (706.5 in^2 from each of the two 30" trunks and 660 in^2 from the 29" trunk) less the replacement tree size of 33.17 in^2 equals 2,040 in^2. The Basic Tree Cost is 2,040 in^2 x the Unit Tree Cost of \$45/in^2 + the Installed Tree Cost of \$1,492.65 which equals \$93,293. The final **Appraised Value is \$26,900** or the Basic Tree Cost of \$93,293 x the Species rating of 40% x the Condition rating of 90% x the Location rating of 80%.

Tree #648 is a California [Peruvian] Pepper (S*chinus molle*), with a condition rating of 75% as the tree is adjacent to well equipment and an access road. It has a trunk circumference of 113" from one trunk comprising a 36" diameter. It has a location rating of 60% and a species rating of 50%. The adjusted appraised trunk area is 974 in^2 less the replacement tree size of 23.75 in^2 equals 950.25 in^2. The Basic Tree Cost is 950.25 in^2 x the Unit Tree Cost of \$45/in^2 + the Installed Tree Cost of \$1,472.50 which equals \$44,234. The final **Appraised Value is \$10,000** or the Basic Tree Cost of \$44,234 x the Species rating of 50% x the Condition rating of 75% x the Location rating of 60%.

VIII. Mitigations

The Ventura County Tree Protection Ordinance requires the replacement of lost protected trees on a cross-sectional area basis. Thus for trees removed, the appraised trunk areas listed above must equal the cumulative area cross-section of replacement trees (species of replacement trees do not necessarily have to be the same as the species removed) or financial contributions can be made to appropriate agencies based on tree valuations or a combination of both.

Based on the requirements above, 883 protected trees or other native, drought-tolerant species would need to be added to the project to provide the offsets necessary for the protected trees being removed as they have at least a cumulative cross-sectional area at breast height of 8,491 inches square. There are six trees requiring offsets (#640, #641, #642, #645, #646 & #648) having a cumulative 8,491 square inch area (1,273+1,366+2,719+ 86+2,073+974 inches respectively). With the addition of 883 trees, this offset can be accomplished if the average trunk DBH of each tree is 3.5" (1.75^2 x 3.14 x 883 = 8,491). Since this is not practical, a combination of added trees and offset payments can be made to mitigate the loss of the six trees being removed. If only offset payments are elected, the total would come to **$92,880** ($11,200 + $16,900 + $25,700 + $2,180 + $26,900 + $10,000).

IX. Recommendations

The property owners are seeking a permit for the construction of the Ventura Ranch Farmworker Housing project and access road improvements which would require the removal of six protected trees and encroachment within the protected zones of 4 protected trees. The remaining trees should not suffer adverse impacts provided the following outlined protective measures are adhered to.

X. Tree Protection Plan

To insure that the proposed construction does not result in damage to the protected trees, the following mitigation measures should be implemented during the project:

- Temporary, protective fencing shall be installed at the limit of the tree protection zone—TPZ (5'-0" from the drip line) of each protected tree. When activities occur within the protected zone of a protected tree, the arborist or his designee will temporarily relocate the protective fencing to the limit of the disturbance so that the activities can be conducted. Upon completion, fencing will be moved back to the limit of the protected zone.
- The disturbance areas noted on plans will be observed and areas under protected zone of trees will be temporarily paved with 1" 4' by 8' sheets of plywood to reduce compaction.
- To the extent practicable, activities within the TPZ of a protected tree will be done by hand; however, mechanized equipment may be required for some activities within the protected zone of a tree. Activities performed within the TPZ of a protected tree will be under the supervision of the arborist or his designee.
- The amount of time that exhaust from mechanized equipment will pass within the protected zone of an oak or heritage tree shall be limited to one 8–hour day of exposure followed by 2–days of no exposure. On the days that the equipment is not to be used, the use of hand tools will be allowed.
- The construction area shall be watered during digging, grading, and construction to

minimize dust on the foliage of the trees.

- Protected trees shall be lightly sprayed with water to wash off dust during and after construction as needed and where possible (rain may preclude the need for this).
- Oak & heritage trees shall be protected from any material runoff into their protected zones through the use of temporary fencing and straw wattles upslope from the tree.
- All soil and debris removed from around the crown of the trunk of the trees shall be done by hand.
- Materials, equipment, or liquid contaminates shall not be stored under the TPZ of protected trees.
- In the event protected tree roots are encountered, the arborist or his designee is to be contacted immediately and construction activities in area to be halted. Cutting of oak or Heritage tree roots is prohibited. Cut, nicked, and bruised roots to be treated with fungicide.

In addition to the construction mitigations, we also recommend pruning of deadwood and dieback, thinning out of canopies (not to exceed a 15% reduction), and deep root fertilization.

XI. Conclusions

Twelve trees will require protection for the purposes of the proposed construction. Six protected trees will be removed (along with a number of unprotected trees not included in this report) and four protected trees will have encroachment into their protected zones. Trees may be added to the project and/or contributions may be made to the County tree fund to offset the removal of five Heritage trees and one protected native tree. The remaining protected trees will be minimally impacted by the project. This is due to precautions that will take place to prevent construction from happening within the protected zones of the trees. Where TPZ encroachment is necessary, hand digging will be implemented in these areas. Fencing will prevent machinery and materials from infringing on the protected zone. Trees will be watered, fertilized and treated for pests as needed to encourage health and vigor. Once construction is complete mulch will be added below the drip line to benefit the root system. If implemented as designed, no deleterious effects on the trees should arise from this project.

I certify that all the statements of fact in this report are true, complete, and correct to the best of my knowledge and belief, and that they are made in good faith.

Subject: Review of PL23-0051, Ventura Ranch Farmworker Housing Complex ISBA dated July 22, 2024

Dear Mr. Conger:

Rincon Consultants, Inc. (Rincon) reviewed the PL23-0051 Initial Study Biological Assessment (ISBA) dated July 22, 2025 for adequacy. The following items are required for ISBA completeness:

- While the parcel boundary, proposed internal parcel boundary, grading limits, and proposed fuel modification zones are depicted on figures, proposed structures, proposed roads and road improvements, proposed utility corridors, and other proposed developments included in the project description (including walking paths, hiking trails and parking area within Parcel 4, community gardens, basketball courts, play fields, landscaping) are not depicted on figures in the ISBA. These elements should be included on figures in order to determine the full extent of biological resources impacts associated with the proposed development.
- Completed Combined Vegetation Rapid Assessment and Relevé Field Forms are required to document sensitive vegetation communities observed within the survey area (Page 38 of the Initial Study Assessment Guidelines [ISAG]). These forms shall be sent to the California Department of Fish and Wildlife (CDFW) and included in the ISBA.
- Vegetation community polygons in Figure 3 immediately north and northeast of the Parcel 3 boundary are currently merged together. The green vegetation lines that separate PC1, PC2, and PC17 currently terminate at the "Proposed Internal Parcel Boundary", and therefore the boundaries between PC1, PC2, and PC17 are not fully delineated. Figure 3 should be revised to address this inconsistency.
- During the ISBA Review Site Visit performed by Rincon Biologist Kyle Gern, Mr. Gern determined that Tree No. 3 in the ISBA (currently documented as a silk oak [*Grevillea robusta*]) is actually a blue spruce (*Picea pungens*) tree. In addition, Mr. Gern documented five additional County-protected trees within the grading footprint, including two coast live oaks (*Quercus agrifolia*), two canary island date palms (*Phoenix canariensis*), and one blue gum eucalyptus (*Eucalyptus globulus*). Consistent with the ISBA Guidelines, if impacts to County-protected trees will occur as part of the project, an arborist survey and report should be prepared and submitted to the County.
- The following special status species are documented in the CDFW California Natural Diversity Database (CNDDB) within five miles of the project site, but are not included in the special-status species table on Page 25 of the ISBA. The ISBA should be revised to evaluate the potential for occurrence of the following species, and include mitigation measures if it is determined that any of the species have the potential to be impacted by the project:

  - pallid bat (*Antrozous pallidus*; Occurrence Number [No.] 311)
  - Mexican long-tongued bat (*Choeronycteris mexicana*; Occurrence No. 13)
  - western mastiff bat (*Eumops perotis californicus*; Occurrence No. 93)
  - coastal California gnatcatcher (*Polioptila californica californica*; Occurrence No. 990)
  - monarch - California overwintering population (*Danaus plexippus* pop. 1; Occurrence No.'s 294, 167, 166, 165, 434)
  - California legless lizard (*Anniella* sp. 1; Occurrence No.'s 3, 36, 37)
  - coastal whiptail (*Aspidoscelis tigris stejnegeri*; Occurrence No. 93)
  - western snowy plover (*Charadrius nivosus nivosus*; Occurrence No. 42)
- Please include all wildlife barriers on project figures. Currently there are no mapped wildlife barriers, but they are described on Page 30 of the ISBA.

Please contact Kyle Gern at 805-844-1492 if you have any questions.

Sincerely,
Rincon Consultants, Inc.

Subject: Historical Resources Assessment for the Ventura Ranch Farmworker Housing Complex Project in Unincorporated Ventura County, California

Dear Ms. Butler:

The County of Ventura (County) retained Rincon Consultants, Inc. (Rincon) to prepare this historical resources assessment in support of the Ventura Ranch Farmworker Housing Complex Project (project), located in unincorporated Ventura County, California. This letter report documents the methods and results of the tasks conducted by Rincon as part of the assessment, including a site visit, research, and evaluation of one property for historical resources eligibility. All work was completed in accordance with the California Environmental Quality Act (CEQA) and local regulations, including the County's *Initial Study Assessment Guidelines*.

Rincon Cultural Resources Principal Shannon Carmack, provided management oversight for this historical resources assessment. Senior Architectural Historian Rachel Perzel, MA, conducted the field survey and archival research and provided management oversight. Architectural Historian James Williams, MA, conducted archival research and is the primary author of this letter report. All of the professionals noted above meet the Secretary of the Interior's Professional Qualifications Standards for history and architectural history (National Park Service 2025). Geographic Information Systems Analyst Abby Robles prepared the figures found in this report. Ms. Carmack and Ms. Perzel reviewed this letter report for quality control.

Project Site and Description

The approximately 83-acre project site is located north of Floral Drive and east of North Ventura Avenue (Assessor's Parcel Numbers [APNs] 063-0-110-065, -035, -090, and -145), in unincorporated Ventura County. Roughly 3.62 miles north of the City of Ventura, the project site is within the City's sphere of influence. It currently contains primarily undeveloped open space and minimal remnants of orchard trees on multiple properties. However, a developed area in the west of the project site in proximity to north Ventura Avenue includes a single-family residence, several outbuildings, and other associated built features; the orchard once located on the property has been almost entirely removed. Single-family residential uses and open space are located to the north, with undeveloped open space to the east, single-family and agricultural uses to the south, and Highway 33 to the west, across from which is vacant industrial land. Attachment 1, Figure 1 shows the regional project site location, and Figure 2 shows a more detailed view of the project site.

The proposed project involves the demolition of the existing residential and agricultural buildings located on APN 063-0-110-065-090 (4884 North Ventura Avenue, subject property) and the subdivision of the property into four parcels: two parcels totaling 19.6-acres that would be developed into an affordable housing complex, an approximately 53-acre conservation parcel that would remain

open space, a 10-acre private agricultural parcel for continued agricultural production. The proposed parcels are illustrated in the Tentative Parcel Map shown in Attachment 1, Figure 3.

The project would include 328 residential units within 18 buildings, developed in two phases. Phase 1 would consist of 180 units within 10 residential buildings on 10.12-acres. Phase 2 would consist of 148 units within eight residential buildings on 9.47-acres. The development would also include one free standing community center, a second community center within one of the residential buildings, two maintenance buildings, and eight trash enclosures. Residential amenities would include play fields, a teen/adult recreation amenity, playground equipment, a community garden, walking paths, and electric vehicle charging stations. The proposed project would feature a community center with an active area in the northwestern corner, a playground for children aged five to twelve in the southeastern corner, another playground for children aged two to five in the southeastern corner, and a central green recreation plaza located near the heart of the residential site. In addition, 2.62 miles of trails and a parking area with 12 parking spaces would be added to the conservation parcel and would be available for public use.

The proposed buildings would feature a combination of one, two and three stories, with a maximum height of 35 feet. The proposed buildings would be designed in a modern Spanish Colonial style with tile roofing, dark vinyl windows, beige cement plaster, dark brown gutters and downspouts, light brown beams, rafter tails and doors, and decorative tiles. Attachment 1, Figure 4 depicts the conceptual site plan.

Methods

Background and Archival Research

Rincon completed background and archival research in support of this assessment throughout February, March, and April 2025. A variety of primary and secondary source materials were consulted. Sources included, but were not limited to, historical maps, aerial photographs, and written histories of the area. The following sources, in addition to those listed in the *References* section, were utilized to develop an understanding of the project site and its context:

- Ventura County Assessor's Office
- Probate court and deed documents provided by the County of Ventura
- Historical aerial photographs accessed via NETR Online
- Historical aerial photographs accessed via University of California, Santa Barbara Library FrameFinder
- Sanborn Fire Insurance Company Maps accessed through the Los Angeles County Public Library
- Historical USGS topographic maps
- County of Ventura Building Permits accessed via the County of Ventura Building and Safety Division]
- Historical city directories obtained via Environmental Risk Information Services (Environmental Risk Services [ERIS] 2025)

Field Survey

Rincon Senior Architectural Historian Rachel Perzel, MA, conducted a built environment survey of the project site on February 20, 2025. Built environment resources within the project site, including buildings, structures, and associated agricultural and landscape elements, were visually inspected. Pursuant to California Office of Historic Preservation (OHP) Guidelines (California OHP 1995), properties over 45 years of age were recorded on California Department of Parks 523 series forms (DPR forms) and evaluated for inclusion in the National Register of Historic Places (NRHP), the California Register of Historical Resources (CRHR), and for local designation as a Ventura County Landmark, Structure of Merit, and Point of Interest. During the survey, the overall condition and integrity of these resources were documented and assessed. Site characteristics and conditions were documented using notes and digital photographs which are maintained at our Rincon Ventura office. Rincon did not complete an archaeological survey as part of the current analysis.

Historical Context

The following historical context is presented to support the historical resources evaluation included in the *Findings* section.

COUNTY OF VENTURA

The area that is now Ventura was missionized in 1782, with the founding of San Buenaventura, which became a secularized parish in 1836 (California Mission Resource Center 2019). The townsite of San Buenaventura (referred to as Ventura following 1889) was first laid out by Jose Arnaz in 1848 and became an official town when its post office was established in 1864. The city was incorporated by an act of state legislature in 1866. During this early period, the community was primarily accessible via ship and development was clustered in the vicinity of (and north and west of) the mission. In 1868, a stagecoach line was established through the area, followed by the completion of the transcontinental railroad in 1869. After these developments, San Buenaventura's downtown area became denser and diversified to include varying ethnic backgrounds, including Italian, French, German/Austrian and Chinese, many of whom established commercial enterprises (Historic Resources Group 2007).

In 1873, Ventura County was created from Santa Barbara County, comprising over 1,000,000 acres of land along the coast (Gidney et al. 1917). After its creation, hundreds of people moved to the area, and development such as the construction of a new schoolhouse and a county courthouse began to take shape. The construction of a wharf was the first large-scale infrastructural improvement undertaken in the city and county of Ventura. Construction began in 1872 and was completed the following year (January 1, 1873), spurring economic growth in the city and surrounding region. At the time of its construction, the wharf in Ventura was the longest wooden wharf in California (City of Ventura n.d.). Its presence not only increased the city's general accessibility but perhaps more importantly, it provided much needed shipping options for the county's already established and growing agricultural economy, including the lumber and oil industries (Historic Resources Group 2007, Triem 1982). The surrounding area north of the city developed as agricultural land during this period with only a few large Victorian farmhouses constructed in association with the fields.

Following the turn of the century, the city of Ventura greatly expanded its geographic boundaries. During this period, significant portions of recently annexed land remained in use for agricultural purposes and commercial and residential development in the downtown area persisted. North of the city, oil was discovered along the hills and large oil fields were constructed by locals and national oil companies (Historic Resources Group 2007). A significant strike by Shell Oil in 1921 ushered in exponential growth in both the city and the county and expansive residential development took place. This development occurred throughout the county but particularly surrounding the oil fields. Within the area surrounding the project site, small residential developments popped up to house oil workers and their families, replacing some of the agricultural fields. While growth slowed during the Depression and lead up to World War II, the postwar period ushered in tremendous growth. With greater reliance on the automobile, the city expanded east of downtown. In September 1962, U.S. Highway 101 was constructed, trending east-west along the ocean, with Highway 33 and 126 constructed in the same decade (Historic Resources Group 2007). Highway 33 replaced North Ventura Avenue as the main connector between Ventura and Ojai. During this period, some agricultural properties in the area surrounding the project site were sub-divided for small residential tracts, commercial buildings along Ventura Avenue, and the Pepsi Bottling Plant. Despite the development of the latter half of the twentieth century, the area continues to retain a substantially rural character.

Findings

The following section summarizes the results of all background research and fieldwork as they pertain to built environment resources that may qualify as historical resources. The field work and background research resulted in the identification of one historic-age property within the project site: the subject property, 4884 North Ventura Avenue (Attachment 1, Figure 5). This property was recorded and evaluated for historical resources eligibility on DPR series 523 forms, which are included in Attachment 2 and summarized below.

4884 North Ventura Avenue

Physical Description

The subject property consists of a single-family residence, detached garage, shed, barn, and shipping container building situated on an 18.24-acre agricultural property. The residence, garage, and shed form a cluster of buildings situated near the property's southwest corner and western boundary, which fronts North Ventura Avenue. Southeast of the residential complex is the barn, and further east is the shipping container building.

The residence, which exhibits elements of the Ranch style, rises one story from a U-plan and concrete perimeter foundation to culminate in a cross-gabled roof with wide overhangs and composition shingles (Attachment 1, Figure 6,Figure 7, Figure 8). Its wood-frame structural system is clad principally in horizontal wood lap siding, with vertical planks with scalloped ends featured in the gable ends. Entrances are located on the south (front) and north elevations. The front entrance is sheltered by a broad extension of the eave and features a solid wood front door. Secondary entrances feature wood and sliding glass doors. Windows generally feature non-original, horizontally sliding vinyl sashes in varying sizes; however, two original octagonal fixed windows with textured glass panes flank the front door. Additional details include the wide front porch with brick steps and flooring, modestly shaped fascia on the gable ends, a fieldstone clad internal chimney, a walled in rear patio, and a breezeway connecting the residence to the garage, adjacent to the east. Immediately behind the residence, there

is a fieldstone-paved court, around which the garage and shed are also situated. The house is in good condition and appears to generally retain integrity to its original construction.

The detached garage shares many of the architectural qualities of the residence, including compact, one-story massing; a gabled roof with wide overhangs and shaped fascia; and horizontal and vertical wood exterior wall cladding (Attachment 1,Figure 9). A non-original metal roll-up garage door opens to the south, accessing an asphalt paved driveway.

The shed is a one-story, rectangular-planned building facing the north side of the court (Attachment 1, Figure 10). It is capped with a corrugated-metal-clad, side-gabled roof, which extends broadly to the west to shelter an open area accounting for approximately one half of the building's total footprint. Siding consists of vertical wood planks, and a vertical-wood-plank door opens on the south elevation.

The barn is located approximately 150 feet southeast of the residence (Attachment 1, Figure 11). It is a utilitarian building with an irregular footprint, concrete foundation, and a gabled and pent roof with corrugated metal cladding. Exterior walls are clad in T1-11 siding. Located on multiple elevations, entrances are accessed via non-original roll-up metal doors. Livestock pens are located immediately east and west of the building.

Located approximately 60 feet northeast of the barn is the shipping container building consisting of three adjoining steel shipping containers (Attachment 1, Figure 12). On the west elevation, one of the shipping containers was modified to include unpainted wood-plank siding, a trio of large 3-over-3 wood-sash casement windows, and a wood door with diamond glazing. Other modifications include a side door, air conditioning unit, and circuit breaker box on the west elevation.

Landscaping in the vicinity of the residential complex consists primarily of a large front lawn and mature trees, including a row of trees lining the property's Ventura Avenue frontage. Much of the remainder of the property is occupied by a large, open agricultural field (Attachment 1, Figure 13). Although the parcel was historically planted as an orchard, nearly all the orchard trees have been removed from the property. A row of mature trees forms a windbreak along the property's North Ventura Avenue frontage, while a modern oil pumpjack is located along the private drive, near the southwest corner of the property.

PROPERTY HISTORY

The subject property was likely used for agriculture by sometime around the turn of the twentieth century. This is suggested by the 1904 edition of the USGS *Ventura, CA* topographical map, which shows the subject property without any buildings or structures and the area surrounding the property characterized by scattered buildings located along North Ventura Boulevard in a pattern suggestive of moderately sized farms (USGS 2025). The earliest property owners confirmed in research for this study, were Mae and Henry Goldstone who held a one-half interest in the property as mortgagees, with mortgagor Morris Cohn owning the other half, as listed in an 1898 newspaper item (Ventura Weekly Post and Democrat 1898).

The research conducted in support of this assessment did not find any information of consequence regarding Mae and Henry Goldstone. Maps included in the *Historical Atlas of Ventura County* suggest that Morris Cohn owned the subject property outright by 1912 (Alexander 1912). Cohn, who was notable as one of the earliest Jewish residents of Ventura County was most closely associated with the Saticoy area, where he established a general store in the 1870s (San Buenaventura Research Associates 2014). After his death in 1915, the subject property was among 15 pieces of real estate in Ventura, Los Angeles, and San Francisco counties he passed to his wife Emilie (California Superior Court 1916). In 1926, Emilie's heirs Annie Feder and Emile Kahn inherited the property jointly, with Feder as the sole trustee (California Superior Court 1926). A historical aerial photograph taken in 1939

shows a residence (no longer extant) was present at the southwest corner of the property, with an orchard occupying the rear half of the property at the time (UCSB 1939).

In 1943, Feder sold the property to Harold A. and Jeanette (née Righetti) Barnard. The Barnard family's roots in Ventura County go back to 1868, when Austin Denny Barnard, Sr. and Sarah E. Barnard relocated their family to the area from Oregon (Storke 1891) In addition to business interests in ranching, real estate, and lumber, the Barnard family was responsible for discovering oil in the Ventura Avenue area around 1885 and indirectly precipitating the exploration that led to Ventura oil boom of the 1920s (Storke 1891, Galvin Preservation Associates 2011). However, whatever the potential significance of the Barnard family in the context of the early Anglo-American development of the area, the research conducted for this assessment did not indicate the family had any direct associations with the subject property prior to Harold and Jeanette's acquisition of it in 1943, well after the early period of Anglo-American development, when the Barnard family first established their importance in local business.

Historical aerial photographs show that by 1945, Harold and Jeanette Barnard had demolished the residence located at the southwest corner of the property (UCSB 1939, 1945). Circa 1959, the Barnards constructed the existing residence, shed, and detached garage in the same location as the previous house, in addition to building the existing barn in its current location (NETR Online 2025). By 1967, the house, shed, and detached garage were relocated approximately 200 feet to the northeast to their present location, while the barn remained in its current location (NETR Online 2025). A review of historical aerial photographs suggests the relocation was completed in conjunction with the construction of Highway 33 and the associated realignment of North Ventura Avenue; aerial photographs show that to accommodate an underpass a bend was constructed on North Ventura Avenue that routed the road through what was previously the west end of the Barnard's property, where the residence was originally sited (NETR Online 2025).

A lifelong resident of the Ventura area, Harold Barnard died in 1972 (Ventura County Star 1972). Historical building permits for the property show Jeanette remained an occupant and/or owner of the property until at least as recently as 1982 (County of Ventura Building and Safety Division 1982). Historical city directories list Robert Barnard at the address from 1980 to 2003. Other individuals and entities associated with the address include Dean Vandset, Jack Vadset, and Finch Farms (ERIS 2025; County of Ventura Building and Safety Division 2004). The shipping container building was placed on the property sometime after 2022, and circa 2023, nearly all orchard trees on the property were removed from the property, leaving a few rows of trees at the far east end of the parcel (NETR Online 2025, Google Earth 2025).

HISTORICAL RESOURCES EVALUATION

The subject property was previously recorded in 2024 by Wayne Bischoff of Envicom (Bischoff 2024). The 2024 record categorizes the property as a Traditional Ranch-style residence and concludes that the property lacks sufficient architectural quality for listing in the CRHR. The evaluation does not address all built environment features on the property, nor does it specify any CRHR criteria or present an evaluation for eligibility for inclusion in the NRHR or for local designation in Ventura County.

The following significance evaluation is the result of the site survey and archival research conducted by Rincon in 2025. As a result of the current assessment, the subject property is recommended ineligible for listing in the NRHP or CRHR or for designation as a County of Ventura Landmark, Structure of Merit, or Point of Interest.

The subject property is located in a historically agricultural area in unincorporated Ventura. Although the property has served as a farm-residence since at least the 1930s, and possibly since the turn of the century, all extant buildings currently on the property date to between circa 1959 and circa 2023.

Research for this study found no evidence that agriculture in this area during the mid-twentieth century was part of any important historical pattern. As such, the property's associations with Ventura-area agriculture are not historically significant. The current assessment did not indicate that the subject property may be associated with any other potentially significant trends or events. It is therefore recommended ineligible for listing in the NRHP under Criterion A, the CRHR under Criterion 1, and as a Ventura County Landmark under Criterion 1.

Research conducted for the current assessment found the subject property was previously owned by three families associated with late-nineteenth-century Anglo-American development in Ventura County, the Goldstones, Cohns, and Barnards. Research for this study did not find Mae and Henry Goldstone possess demonstrably important historical contributions, and in any case, are not associated with any built environment element remaining on the property. Although Morris Cohn may be significant as an early and accomplished member of Ventura County's Jewish community, his arguably significant business activities were rooted in the Saticoy area. Furthermore, the subject property was but one among many he acquired throughout the state of California and is not known to have been of particular significance to his contributions as a settler or businessman. Additionally, although the Barnard family may have made significant contributions to local history in areas including ranching, lumber, and oil extraction, such contributions were made in the late nineteenth century, predating Harold and Jeanette Barnard's ownership of the property and the construction in circa 1959 of the extant historic-age built environment features. Moreover, research for this study did not find that Harold and Jeanette, despite their family's accomplishments, made any notable historical contributions. Research for this study found no evidence that any other owner or occupant of the property has made significant historical contributions to the county, region, state, or nation. Therefore, the subject property is recommended ineligible for listing in the NRHP under Criterion B, the CRHR under Criterion 2, and as a Ventura County Landmark under Criterion 2.

Architecturally, the subject property consists of a Ranch-style residence and three additional buildings constructed in the 1950s, in addition to the shipping container building constructed circa 2022. Although the residence exhibits several character-defining features of the Ranch style, such as an asymmetrical composition, gabled roof, and exposed rafter tails, it is not distinguished by any of its elements or its overall design and construction; rather, it is a relatively ordinary example of the style. The remaining buildings on the property are of undistinguished, functional design and are typical of residential and agricultural ancillary buildings found throughout the state. The property as a whole is also not significant as an example as a farm-residence property; it is not notable for its planning and suffers a lack of design integrity due to the loss of the historical orchard trees. Therefore, the property does not embody the distinctive characteristics of a type, period or method of construction, or represent the work of a master, or possess high artistic values, or represent a significant and distinguishable entity whose components may lack individual distinction. It is therefore recommended ineligible for listing in the NRHP under Criterion C, the CRHR under Criterion 3, and as a Ventura County Landmark under Criterion 3.

The history of agriculture in Ventura is well-documented in secondary-source literature, and the subject property is unlikely to yield information pertaining to the subject. It is therefore recommended ineligible for listing in the under NRHP Criterion D, the CRHR under Criterion 4, and as a Ventura County Landmark under Criterion 4).

Based on the analysis above, the subject property is also recommended ineligible as a Ventura County Structure of Merit or Point of Interest. Specifically, it does not meet Structure of Merit requirements because, although it retains integrity (Criterion 3), it is not a site of historical, architectural, community, or aesthetic merit (Criterion 1) or a Board of Supervisors-approved surveyed site with a National Register status code of 1 through 5 (Criterion 2). Finally, the subject property does not qualify as a Point of Interest because it is not the site of a building, structure or object that no longer exists, but

was associated with historic events, important persons, or embodied a distinctive character or architectural style (Criterion 1); or a site that has historical significance, but has been altered to the extent that the integrity of the original workmanship, materials, or style has been substantially compromised (Criterion 2); or the site of a historic event which has no distinguishable characteristics other than that a historic event occurred at that site, and the site is not of sufficient historical significance to justify the establishment of a Landmark (Criterion 3).

Conclusions and Recommendations

Historical Built Environment Resources

This assessment identified one built-environment historical resource within the project site, 4884 North Ventura Avenue. As a result of the current study, the property is recommended ineligible for listing in the NRHP, CRHR, and for designation as a Ventura County of Ventura Landmark, Structure of Merit, or Point of Interest. As such, the property is not considered a historical resource pursuant to CEQA and its demolition would result in ***no impact to historical resources*** pursuant to CEQA.

Should you have any questions concerning this study, please do not hesitate to contact the undersigned at 805-946-1931 or jwilliams@rinconconsultants.com.

Period of Significance 1959 **Property Type** Residential and agricultural **Applicable Criteria** N/A
(Discuss importance in terms of historical or architectural context as defined by theme, period, and geographic scope. Also address integrity.)

The subject property is recommended ineligible for listing in the National Register of historic Places (NRHP) or California Register of Historical resources (CRHR) or for designation as a County of Ventura Landmark, Structure of Merit, or Point of Interest. The property was likely used for agriculture by sometime around the turn of the twentieth century. This is suggested by the 1904 edition of the USGS Ventura, CA topographical map, which shows the subject property without any buildings or structures and the area surrounding the property characterized by scattered buildings located along North Ventura Boulevard in a pattern suggestive of moderately sized farms (USGS 2025). The earliest property owners confirmed in research for this evaluation, were Mae and Henry Goldstone who held a one-half interest in the property as mortgagees, with mortgagor Morris Cohn owning the other half, as listed in a contemporary newspaper item (Ventura Weekly Post and Democrat 1898).

P3a. Description (Continued):

The detached garage shares many of the architectural qualities of the residence, including compact, one-story massing; a gabled roof with wide overhangs and shaped fascia; and horizontal and vertical wood exterior wall cladding (Photograph 4). A non-original metal roll-up garage door opens to the south, accessing an asphalt paved driveway.

The shed is a one-story, rectangular-planned building facing the north side of the court (Photograph 5). It is capped with a corrugated-metal-clad, side-gabled roof, which extends broadly to the west to shelter an open area accounting for approximately one half of the building's total footprint. Siding consists of vertical wood planks, while a vertical-wood-plank door opens on the south elevation.

The barn is located approximately 150 feet southeast of the residence (Photograph 6). It is a utilitarian building with an irregular footprint, concrete foundation, and a gabled and pent roof with corrugated metal cladding. Exterior walls are clad in T1-11 siding. Located on multiple elevations, entrances are accessed via non-original roll-up metal doors. Livestock pens are located immediately east and west of the building.

Located approximately 60 feet northeast of the barn is the shipping container building consisting of three adjoining steel shipping containers (Photograph 7). On the west elevation, one of the shipping containers was modified to include unpainted wood-plank siding, a trio of large 3-over-3 wood-sash casement windows, and a wood door with diamond glazing. Other modifications include a side door, air conditioning unit, and circuit breaker box on the west elevation.

Landscaping in the vicinity of the residential complex consists primarily of a large front lawn and mature trees, including a row of trees lining the property's Ventura Avenue frontage. Much of the remainder of the property is occupied by a large, open agricultural field (Photograph 8). Although the parcel was historically planted as an orchard, nearly all the orchard trees have been removed from the property. A row of mature trees forms a windbreak along the property's North Ventura Avenue frontage, while a modern oil pumpjack is located along the private drive, near the southwest corner of the property.

B10. Significance (Continued):

The research conducted in support of this evaluation did not find any information of consequence regarding Mae and Henry Goldstone. Maps included in the Historical Atlas of Ventura County suggest that Morris Cohn owned the subject property outright by 1912 (Alexander 1912). Cohn, who was notable as one of the earliest Jewish residents of Ventura County was most closely associated with the Saticoy area, where he established a general store in the 1870s (San Buenaventura Research Associates 2014). After his death in 1915, the subject property was among 15 pieces of real estate in Ventura, Los Angeles, and San Francisco counties he passed to his wife Emilie (California Superior Court 1916). In 1926, Emilie's heirs Annie Feder and Emile Kahn inherited the property jointly, with Feder as the sole trustee (California Superior Court 1926). A historical aerial photograph taken in 1939 shows a residence (no longer extant) was present at the southwest corner of the property, with an orchard occupying the rear half of the property at the time (UCSB 1939).

In 1943, Feder sold the property to Harold A. and Jeanette (née Righetti) Barnard. The Barnard family's roots in Ventura County go back to 1868, when Austin Denny Barnard, Sr. and Sarah E. Barnard relocated their family to the area from Oregon (Storke 1891) In addition to business interests in ranching, real estate, and lumber, the Barnard family was responsible for discovering oil in the Ventura Avenue area around 1885 and indirectly precipitating the exploration that led to Ventura oil boom of the 1920s (Storke 1891, Galvin Preservation Associates 2011). However, whatever the potential significance of the Barnard family in the context of the early Anglo-American development of the area, the research conducted for this evaluation did not indicate the family had any direct associations with the subject property prior to Harold and Jeanette's acquisition of it in 1943, well after the early period of Anglo-American development, when the Barnard family first established their importance in local business.

Historical aerial photographs show that by 1945, Harold and Jeanette Barnard had demolished the residence located at the southwest corner of the property (UCSB 1939, 1945). Circa 1959, the Barnards constructed the existing residence, shed, and detached garage in the same location as the previous house, in addition to building the existing barn in its current location (NETR Online 2025). By 1967, the house, shed, and detached garage were relocated approximately 200 feet to the northeast to their present location, while the barn remained in its current location (NETR Online 2025). A review of historical aerial photographs suggests the relocation was completed in conjunction with the construction of Highway 33 and the associated realignment of North Ventura Avenue; aerial photographs show that to accommodate an underpass a bend was constructed on North Ventura Avenue that routed the road through what was previously the west end of the Barnard's property, where the residence was originally sited (NETR Online 2025).

A lifelong resident of the Ventura area, Harold Barnard died in 1972 (Ventura County Star 1972). Historical building permits for the property show Jeanette remained an occupant and/or owner of the property until at least as recently as 1982 (County of Ventura Building and Safety Division 1982). Historical city directories list Robert Barnard at the address from 1980 to 2003. Other individuals and entities associated with the address include Dean Vandset, Jack Vadset, and Finch Farms (ERIS 2025; County of Ventura Building and Safety Division 2004). The shipping container building was placed on the property sometime after 2022, and circa 2023, nearly all orchard trees on the property were removed from the property, leaving a few rows of trees at the far east end of the parcel (NETR Online 2025, Google Earth 2025).

Historical Significance Evaluation

The subject property was previously recorded in 2024 by Wayne Bischoff of Envicom (Bischoff 2024). The 2024 record categorizes the property as a Traditional Ranch-style residence and concludes that the property lacks sufficient architectural quality for listing in the CRHR. The evaluation does not address all built environment features on the property, nor does it specify any CRHR criteria or present an evaluation for eligibility for inclusion in the NRHR or for local designation in Ventura County.

The following significance evaluation is the result of the site survey and archival research conducted by Rincon in 2025. As a result of the current evaluation, the subject property is recommended ineligible for listing in the NRHP or CRHR or for designation as a County of Ventura Landmark, Structure of Merit, or Point of Interest.

The subject property is located in a historically agricultural area in unincorporated Ventura. Although the property has served as a farm-residence since at least the 1930s, and possibly since the turn of the century, all extant buildings currently on the property date to between circa 1959 and circa 2023. Research for this study found no evidence that agriculture in this area during the mid-twentieth century was part of any important historical pattern. As such, the property's associations with Ventura-area agriculture are not historically significant. The current evaluation did not indicate that the subject property may be associated with any other potentially significant trends or events. It is therefore recommended ineligible for listing in the NRHP under Criterion A, the CRHR under Criterion 1, and as a Ventura County Landmark under Criterion 1.

Research conducted for the current evaluation found the subject property was previously owned by three families associated with late-nineteenth-century Anglo-American development in Ventura County, the Goldstones, Cohns, and Barnards. Research for this study did not find Mae and Henry Goldstone possess demonstrably important historical contributions, and in any case, are not associated with any built environment element remaining on the property. Although Morris Cohn may be significant as an early and accomplished member of Ventura County's Jewish community, his arguably significant business activities were rooted in the Saticoy area. Furthermore, the subject property was but one among many he acquired throughout the state of California and is not known to have been of particular significance to his contributions as a settler or businessman. Additionally, although the Barnard family may have made significant contributions to local history in areas including ranching, lumber, and oil extraction, such contributions were made in the late nineteenth century, predating Harold and Jeanette Barnard's ownership of the property and the construction in circa 1959 of the extant historic-age built environment features. Moreover, research for this study did not find that Harold and Jeanette, despite their family's accomplishments, made any notable historical contributions. Research for this study found no evidence that any other owner or occupant of the property has made significant historical contributions to the county, region, state, or nation. Therefore, the subject property is recommended ineligible for listing in the NRHP under Criterion B, the CRHR under Criterion 2, and as a Ventura County Landmark under Criterion 2.

Architecturally, the subject property consists of a Ranch-style residence and three additional buildings constructed in the 1950s, in addition to the shipping container building constructed circa 2022 Although the residence exhibits several character-defining features of the Ranch style, such as an asymmetrical composition, gabled roof, and exposed rafter tails, it is not distinguished by any of its elements or its overall design and construction; rather, it is a relatively ordinary example of the style. The remaining buildings on the property are of undistinguished, functional design and are typical of residential and agricultural ancillary buildings found throughout the state. The property as a whole is also not significant as an example as a farm-residence property; it is not notable for its planning and suffers a lack of design integrity due to the loss of the historical orchard trees. Therefore, the property does not embody the distinctive characteristics of a type, period or method of construction, or represent the work of a master, or possess high artistic values, or represent a significant and distinguishable entity whose components may lack individual distinction. It is therefore recommended ineligible for listing in the NRHP under Criterion C, the CRHR under Criterion 3, and as a Ventura County Landmark under Criterion 3.

The history of agriculture in Ventura is well-documented in secondary literature, and the subject property is unlikely to yield information pertaining to the subject. It is therefore recommended ineligible for listing in the under NRHP Criterion D, the CRHR under Criterion 4, and as a Ventura County Landmark under Criterion 4).

Based on the analysis above, the subject property is also recommended ineligible as a Ventura County Structure of Merit or Point of Interest. Specifically, it does not meet Structure of Merit requirements because, although it retains integrity (Criterion 3), it is not a site of historical, architectural, community, or aesthetic merit (Criterion 1) or a Board of Supervisors-approved surveyed site with a National Register status code of 1 through 5 (Criterion 2). Finally, the subject property does not qualify as a Point of Interest because it is not the site of a building, structure or object that no longer exists, but was associated with historic events, important persons, or embodied a distinctive character or architectural style (Criterion 1); or a site that has historical significance, but has been altered to the extent that the integrity of the original workmanship, materials, or style has been substantially compromised (Criterion 2); or the site of a historic event which has no distinguishable characteristics other than that a historic event occurred at that site, and the site is not of sufficient historical significance to justify the establishment of a Landmark (Criterion 3).

4884 North Ventura Avenue is a historical residential building that has excellent integrity, but few decorative and no unique architectural details that can be attributed to a particular architectural style or school other than as a Mid-Century residential ranch house. The roof ends and gable faces have modest architectural details of no particular style tradition. The free-standing garage, front porch, and breezeway are original to the house, however, the backyard area enclosure is not; the original house plans indicating that only flagstones were present. It is unknown when the backyard enclosure was constructed, but appears to be during the 1960s, based on the cinderblock type used. The associated barn is entirely functional in design and has no unique style elements. The Ventura County building record does not indicate an architect for the ranch house, and the "R and G" builder of the structure is not found in the historical record.

The 4884 North Ventura Avenue residential building would fall under the SurveyLA Ranch House Style (1930 to 1975) category, which is one of the most common residential architectural styles found in California. More specifically, the structure would fall into their "Traditional Ranch House" sub-category as it has no common Modernism elements. Based on the SurveyLA criteria for Traditional Ranch Houses to be considered as potentially eligible for inclusion in the California Register of Historical Resources, the 4884 North Ventura Avenue property does not have a high quality of architecture that makes it stand out from other ranch houses of the same era, does not appear to have been designed nor built by a master architect, is not constructed of unique materials, and does not vary distinctively from the ranch style pattern seen across much of California during the 1950s.

Geological and Geotechnical Engineering Study
Proposed Farmworker Housing Development
4884 N. Ventura Avenue
Ventura, California

In accordance with our proposal and your authorization, Advanced Geotechnical Services, Inc., (AGS) has prepared this geological and geotechnical engineering study report for the proposed farmworker housing development to be constructed at the subject site. This report presents the results of our data research, site reconnaissance, subsurface exploration, laboratory testing, and our professional opinions regarding the geological and geotechnical engineering factors that may affect the proposed development.

Based on the results of this study, it is our opinion that the site is *suitable* for construction of the proposed development, with some modifications to the proposed scope and plans that were provided to our office, as discussed herein. The recommendations contained within this report should be properly incorporated in the design, and implemented during construction.

This opportunity to be of service is sincerely appreciated. This report should be read from cover to cover to understand its limitations and to avoid taking a recommendation out-of-context. If you have any questions, or if we may be of any further assistance, please do *not* hesitate to call. We look forward to being of continued service.

Respectfully submitted,
Advanced Geotechnical Services, Inc.

1. INTRODUCTION

1.1 General Remarks

This geological and geotechnical engineering study has been prepared for the proposed farmworker housing development to be constructed at the subject site. The purposes of this study are to (1) identify onsite soil and geologic conditions that may affect the proposed project, (2) evaluate the seismicity of the site and potential seismic hazards, and (3) provide geotechnical recommendations for development of the site. This report presents the findings of our data review, subsurface exploration, laboratory testing, engineering analyses and evaluations, and our conclusions and recommendations.

Appendices are attached following the main report. Appendix A includes details related to the field exploration program, and the boring and test pit logs; Appendix B includes the laboratory test results; Appendix C includes the seismic design criteria; Appendix D includes the references used in this study, and the Figures and Plates referenced in this report are included in Appendix E.

1.2 Scope of Services

This geotechnical engineering study included:

a. Site observation and review of geotechnical and geologic data related to the general study area. A *Site Location Map*, based upon a recent aerial image obtained from the interactive web program Google Earth (2022), which shows a broad view of the general area where the subject site is located is provided as Figure 1, and an *Existing Site Plan*, which is based upon an aerial image dated December 2019, obtained from the interactive County View web program maintained by the County of Ventura (2022), showing a more detailed view of the site, is provided as Plate 1. A *Topographic Site Plan*, based upon a recent topographic plan provided by Jensen Design and Survey, Inc., is included as Plate 2.

b. Review of the project plan provided to our office by Jensen Design and Survey, Inc., which consisted of a *Preliminary Grading Plan for Ventura Ranch*, dated July 25, 2022. A copy of this plan has been utilized as the base map for the *Proposed Site Plan*, which is included as Plate 3 of this report.

c. Reconnaissance of the subject site and in the immediate vicinity of the subject site.

d. The excavation, sampling, and logging of 5 borings and 16 test pits for geological and geotechnical evaluation, and 4 test pits for infiltration testing. The borings and test pits extended to depths ranging between approximately 5 and 50.5 feet below the existing ground surface. The borings were excavated utilizing a truck-mounted, 8-inch diameter hollow-stem auger drilling equipment, and the test pits were excavated utilizing a backhoe. The exploratory boring and test pit locations were determined in the field using a tape measure, and approximate reference points, and their approximate locations are shown on the attached Plates 1, 2 and 3, titled *Existing Site Plan*, *Topographic Site Plan*, and *Proposed Site Plan*, respectively. The actual boring and test pit locations may deviate slightly from these locations. The boring and test pit logs are included in Appendix A, along with a general description of the field operations.

e. Laboratory testing of selected samples to determine the engineering properties of the onsite earth materials. The results of the laboratory testing are presented in Appendix B, and on the boring and test pit logs in Appendix A. Soil samples will be *discarded* 30 days after the date of this report, unless this office receives a specific request and fee to retain the samples for a longer period of time.

f. Determination of seismic parameters for potential onsite ground motion, and current building code seismic design parameters.

g. Engineering analysis of the data and information obtained from our field study, laboratory testing, and literature review.

h. Development of geotechnical recommendations for site preparation, grading, building foundations, floor slabs, underground utility trenches, temporary excavations, pavement, stormwater infiltration, and drainage.

i. Preparation of this report summarizing our findings, conclusions, and recommendations regarding the geological and geotechnical aspects of the project site.

The scope of this geotechnical engineering study did *not* include an assessment of potential environmental issues.

1.3 Site Description

The subject site consists of an approximately 18.24-acre sized parcel of land, identified as APN 063-0-110-090, 4884 N. Ventura Avenue, in the unincorporated County area north of the City of Ventura, California, as shown on the attached Figure 1, *Site Location Map*, and Plate 1, *Existing Site Plan*. Figure 1 was created utilizing an image obtained from the Google Earth (2022) online web app, and Plate 1 was created utilizing an image obtained from the Ventura County View (2022) website, utilizing the December 2019 aerial image as a basemap.

At the time of our field exploration program, the majority of the subject site was an actively operating orchard, with an existing single-family residence and barn located in the southwestern corner of the site, as shown on the enclosed *Existing Site Plan*, Plate 1, and *Topographic Site Plan*, Plate 2. The subject site is bounded by existing single-family residences to the north, by Ventura Avenue and Norway Drive to the west, by an existing farm property to the south, with a two-story residence and other miscellaneous structures, and by an undeveloped hillside area to the east.

The general topography of the majority of the subject site (excluding the existing landslide area at the east end of the site, as delineated on the attached Plates 1, 2, and 3, and discussed in greater detail below), slopes gently down towards the west to southwest, with a gradient ranging from a maximum of approximately 7.5% in the northeast corner of this area, to a minimum of approximately 2% in the southwest corner. The existing topographic gradient generally increases from southwest to northeast, with the westernmost portion of the property at an approximate elevation of 203, and the easternmost portion of the property at an approximate elevation of 266, as shown on the *Topographic Site Plan* included as Plate 2.

In the northwestern portion of the site, along Norway Drive, and extending southward along a portion of Ventura Avenue, the grade on the subject site drops abruptly up to a maximum of approximately 6 to 7 feet down towards the property line. Along portions of the north side of the site, various retaining walls up to several feet in height either retain the subject site above the adjacent grades within the backyards of the existing residences, or vice-versa.

The easternmost portion of the subject site begins to slope with an increasing gradient starting at approximate elevation 232, as shown on the *Topographic Site Plan* included as Plate 2. The gradual increase in slope gradient progresses easterly, where in the proximity of the eastern property limits, the slope gradient increases sharply from approximately 3:1 (32%) within the subject site, with the offsite east ascending slope having a gradient locally of as steep as approximately 1:1 (45%), ascending to an approximate elevation of 480 (as determined from Google Earth).

Based upon surficial and topographic expression, our field exploration and reconnaissance efforts, and our review of available historical aerial photographs dating back to January 1927, it is our professional opinion that this east

ascending slope has experienced pre-historic landslide actively, resulting in the existing over-steepened offsite slope and the deposition of landslide debris generated from the landslide event upon this slope and within the easternmost portion of the subject site. The approximate limits of the areas interpreted to be underlain by landslide debris have been indicated on the *Existing Site Plan*, *Topographic Site Plan*, and *Proposed Site Plan* included as Plates 1, 2, and 3, respectively, of this report. More detailed descriptions of this portion of the site, and more in depth discussions of this landslide feature are provided in subsequent sections of this report.

1.4 Proposed Development

The currently proposed development is shown on the attached Plate 3, *Proposed Site Plan*, and consists of a total of 29 two to three-story farmworker housing structures, and surrounding driveways, streets and surface parking. A new roughly east-west trending street will connect to Ventura Avenue in the southwestern portion of the site, and a new roughly north-south trending street near the east end of the site will connect to the existing Floral Drive in the northeastern corner of the site. The attached Plate 3 was created utilizing a *Preliminary Grading Plan for Ventura Ranch*, prepared by Jensen Design and Survey, Inc., dated July 25, 2022. Structural loads for the proposed buildings are not expected to exceed approximately 100 to 150 kips for columns, and 1 to 3 kips per foot for walls.

As will be discussed in more detail in subsequent sections of this report, and as shown on the attached Plates 1 through 3, the extreme eastern end of the site (generally east of the proposed new north-south trending street) has been identified during this study as being within an area that had experienced pre-historic landslide activity, and development within this area should not be permitted. The currently proposed development within this area, as shown on the attached Plate 3, consists of three new housing structures, along with surrounding paved driveway and parking areas. This construction at the east end would require a new retaining wall up to 15 feet in height, and new cut slopes up to approximately 22 feet in height, and a maximum 2:1 gradient. This would require the removal of a large volume of earth materials from the toe of the existing landslide, potentially causing instability. As discussed further in this report, removal of earth materials, and/or construction of new habitable structures in this area should not be allowed, however, portions of this area might be suitable for parking or roadways, provided the final site grade is at or above current existing grades everywhere within this existing landslide impacted area. The three new structures that were proposed to be constructed within this area will have to be relocated to elsewhere on the project site, or eliminated.

Along most of the entire south end of the site, and the eastern portion of the north side of the site, the proposed new site grades will slope relatively gently (gradients less than 5:1) down to meet the current existing grades at the property line, and/or match existing grades. Along the western portion of the north side of the site, the sloping gradient down to the property line increases to as much as approximately 2:1. Along the west side of the site, and along the north and south sides of the new east-west trending street near where it connects to Ventura Avenue, there will be retaining walls up to 5 feet in height at the toe of new descending fill slopes.

The grading currently proposed to be performed within the eastern end of the site, as shown on the *Proposed Site Plan* included as Plate 3 of this report, would require substantial modification in order to avoid destabilizing the existing onsite and offsite slopes present within this area, which have been determined to have been impacted by, and/or are the result of pre-historic landslide activity, and to safely transition to the adjacent existing grade and/or proposed future grades. As noted previously, the removal of materials from this portion of the subject site may destabilize the existing slopes, which currently appear to be in stasis, and therefore the currently proposed cuts and retaining walls should be eliminated from the future grading plans. Additionally, due to the potential of offsite erosion upon the over-steepened offsite slope which may result in soil migration onto the easternmost portion of the subject site, it is recommended that no habitable structures be constructed within the easternmost portion of the site. At a minimum, it is recommended that no removals be made or structures created within that portion of the subject site which lies to the east of the interpreted geologic contact between the older alluvium (Qoa) and the landslide debris (Qls), as identified on Plates 1 through 3 of this report.

Site grading throughout the majority of the site (approximately west of the north-south trending roadway near the east end of the site) will consist of the over-excavation and recompaction of the weaker, upper site soils, and the import of approximately 105,000 additional yards of earth materials to raise the existing site grade approximately 0.5 to 9 feet above the currently existing site grade, to establish grade for the building pads, streets, driveways and parking areas, detention/infiltration basin, and for site drainage. In addition, there will be backfill of related new utilities and retaining walls.

2. GEOLOGIC SETTING

2.1 Geology

Geologic conditions beneath the subject property have been interpreted and characterized based upon our review of published and unpublished references, our review of available historical aerial photographs, our onsite reconnaissance, and our subsurface exploration. Our interpretations involve projections of data and assume that geologic conditions are reasonably constant between points of exposure. Work should continue under the review of the Geologist and Geotechnical Engineer to ensure that geologic conditions different from those described below are recognized and evaluated as soon as possible. Certain subsurface conditions such as groundwater levels and the consistency of near-surface soils will vary with the seasons.

The subject site is located within the Ventura USGS 7.5-minute quadrangle. According to Dibblee (1988), the subject site is underlain by older alluvial materials (Qoa), as shown on the enclosed *Dibblee Regional Geological Map*, Figure 2. According to the *Geologic Map of the Ventura 7.5' Quadrangle* (USGS, 2003), as shown on the attached *USGS Regional Geological Map*, Figure 3, the subject site is underlain by younger alluvial fan deposits classified as Qhf on this map, although the graphical age correlation shows this material as being an 'older' younger alluvial fan material (i.e., within the first half of the Holocene).

Although not identified on the above referenced regional geologic maps, our onsite exploration and reconnaissance programs, and our review of historical aerial photographs indicate that the natural slope which ascends eastward within the eastern portion of the site, continuing offsite with a maximum estimated total slope height of approximately 250 feet, is the result of pre-historic landslide activity. The in-place bedrock material which composes the ascending slope, where exposed in outcrops at the existing ground surface and as encountered in our exploratory excavations, has been determined to consist of Pliocene age sedimentary bedrock of the Pico Formation (Tp and Tps), defined by Dibblee (1988) as consisting of "mostly gray claystone, vaguely bedded, and few thin strata of sandstone" (Tp) and "mostly light gray to tan sandstone, well bedded, in some places pebbly; includes some interbedded claystone, as above" (Tps) and defined by the USGS as "composed of claystone, siltstone, sandstone, locally pebbly; generally susceptible to landsliding". Intact bedrock material, consisting of pebble and cobble rich sandstone materials, are observed to be exposed in the upper most portions of the east ascending slope, and light gray to tan sandstone materials were observed to be exposed in outcroppings located to the north of Test Pit TP-3 and in the bottom of Test Pit TP-2, while olive siltstone was recovered from the bottom of Boring B-3.

Landslide debris is observed to be present at the surface on the lower portions of the east ascending slope, extending westward into the subject site, and was encountered in Borings B-2 and B-3, and Test Pits TP-1 through TP-6, all excavated within the eastern portion of the subject site, and/or the western portion of the adjacent site to the west. The landslide debris was observed to generally consist of silt sand, with minor to abundant gravel and small cobble to small boulder sized inclusions, which is derived from mass wasting of the Pico Formation. The landslide debris appears to mantle the older alluvium (Qoa) in Boring B-2, however it appears that the older alluvium may mantle the landslide debris at the surficial contact indicated on Plates 1 through 3 of this report, which indicates that deposition of the older alluvium began before and continued after the landslide event(s) began and ceased.

More detailed descriptions of the earth materials encountered during the course of our study are provided in the following sections, and in the boring and test pit logs included in Appendix A of this report.

2.2 Faulting

Southern California is a tectonically active region subject to hazards associated with earthquakes and faulting. Faults are classified as either active, potentially active, or inactive. Active faults are defined by the State of California as faults that have exhibited surface displacement within the last 11,000 years. Potentially active faults are defined by the State as those with a history of movement between 11,000 and 1.6 million years ago. Alquist-Priolo Earthquake Fault Zones are zones that have been established by the State that contain active surface fault traces, and projects that are located within these zones require that a fault investigation be performed to determine if active faulting affects the site.

There are no known active, potentially active, or inactive faults mapped on the subject site, and the closest mapped fault to the subject site is the Red Mountain Fault Zone, which is shown by Dibblee as being located as close as approximately 0.82 miles northwest of the subject site, as shown in the upper left corner of the attached *Dibblee Regional Geological Map,* Figure 2. The Red Mountain Fault Zone has been identified as being a thrust fault, with most likely recent surface rupture during the Holocene to Late Quaternary period, and a probable magnitude (M_W) of 6.0 to 6.8 (SCEDC, 2013). This fault, however, is *not* located within an Alquist-Priolo Earthquake Fault Zone.

The attached Figure 4, *Earthquake Fault and Seismic Hazard Zones Map* (CDMG, 1978; CGS, 2003), shows that the area where the subject site is located is not within an Alquist-Priolo Earthquake Fault Zone, or in close proximity to any zones. The nearest Alquist-Priolo Earthquake Fault Zone is located approximately 3.46 miles south of the subject site, further to the south of the area shown on the enclosed Figure 4.

3. EARTH MATERIALS AND SUBSURFACE CONDITIONS

3.1 Older Alluvium (Qoa)

Older alluvial soils were encountered at the ground surface, and extending to the full depths explored throughout the entire roughly level to gently sloping portion of the site, roughly west of the proposed new north-south trending street to be located near the east end of the site. Older alluvial soils may have also been encountered at a depth of approximately 25 feet in Boring B-2, below the landslide debris, and at the ground surface in Test Pit TP-4. The older alluvium encountered near the existing ground surface has been observed to consist predominantly of naturally deposited clayey sand and silty sand, present in a generally slightly moist to moist and dense condition. More detailed earth material profiles are provided on the enclosed boring and test pit logs in Appendix A.

3.2 Landslide Debris (Qls)

Landslide debris was encountered at the ground surface in Borings B-2 and B-3, and Test Pits TP-1 through TP-6, although the material encountered at the ground surface in TP-4 might have been an older alluvium. All of these borings and test pits were excavated within the eastern portion of the study area. The landslide debris was observed to generally consist of silty sand, with minor to abundant gravel and small cobble to small boulder sized inclusions, which is derived from mass wasting of the Pico Formation. The landslide debris was observed to generally be present in a slightly moist and dense condition. More detailed earth material profiles are provided on the enclosed boring and test pit logs in Appendix A.

3.3 Pico Formation Bedrock (Tp)

Bedrock of the late Pliocene age Pico Formation was encountered at a depth of 20 feet in Boring B-3, and at a depth of approximately 3.5 to 5.5 feet (sloping contact) in Test Pit TP-2, and both of these were excavated offsite at the east end of the study area, as indicated on Plate 1 through 3. The bedrock encountered at the bottom of Boring B-3 was observed to consist of olive siltstone, while the bedrock encountered in the bottom of Test Pit TP-2 was observed to consist of white to tan sandstone. Outcroppings visible on the east ascending offsite slope exposed pebble and cobble rich sandstone materials within the uppermost portions of the slope, and tan to light gray sandstone materials were observed to be exposed at the lower portion of the slope.

More detailed earth material profiles are provided on the enclosed boring and test pit logs in Appendix A.

3.4 Soil Parameters

3.4.1 Compaction

Compaction curves were developed in this study for representative samples of the upper onsite soils, to determine the maximum dry density and optimum moisture content, as summarized in the table below. The upper site soils should be over-excavated and recompacted for support of the proposed improvements, as discussed in subsequent sections of this report.

Boring	Depth (ft)	Description	Maximum Dry Density (pcf)	Optimum Moisture Content (%)
B-1	0-5	CLAYEY SAND	121.0	11.0
B-2	0-5	SILTY SAND	126.5	9.0
B-3	0-5	SILTY SAND	129.5	8.0

3.4.2 Compressibility

Consolidation tests were performed on representative undisturbed samples of the onsite soils, and on a remolded sample intended to represent the future compacted fill. The consolidation test results showed a slight to moderate expansion upon inundation with water for some of the samples, negligible to relatively low hydroconsolidation on the remolded sample and majority of the undisturbed samples, and moderate hydroconsolidation on one of the landslide debris samples. Consolidation test results are included in Appendix B.

3.4.3 Shear Strength

Direct shear testing was performed on a remolded sample of the near surface soils to determine the characteristics of a future fill compacted to 90% relative compaction, and on representative undisturbed samples of the native earth materials. The results of the direct shear testing are included in Appendix B.

3.4.4 R-value Testing

A representative sample of the upper site soils was transported to an outside laboratory for R-value testing, and the results are attached in Appendix B. The results showed that the upper site soils have an R-value of 10. Additional R-value testing should be performed on representative samples of the paving subgrade areas throughout the site, at or near the completion of grading, to verify the R-value of the final subgrade soils.

3.4.5 Grain Size Analysis

Grain size testing was performed on representative samples of the earth materials underlying the site by using mechanical sieve analysis, and hydrometer testing. The results of the grain size testing are presented in Appendix B of this report.

3.4.6 Expansion Category

The potential of the soil to swell or expand increases with an increase in soil density, a decrease in initial moisture content (low percent saturation), an increase in clay content, and an increase in the activity of the clay content. Expansive soils change in volume (shrink or swell) due to changes in the soil moisture content. The risk of soil expansion increases with an increase in expansion index.

The expansion indices of the upper site soils were found to be 34, 54 and 87, for samples obtained from Borings B-3, B-2 and B-1, respectively. These expansion values are in the *low* to *medium* expansion category. Expansion index test results are provided on the boring logs in Appendix A.

3.4.7 Corrosivity

The risk of corrosion of construction materials relates to the potential for soil-induced chemical reaction. The rate of deterioration depends on soil resistivity, texture, acidity, and chemical concentration. Representative samples of the upper site soils were transported to an outside laboratory for corrosivity testing, and the results of these tests are attached in Appendix B. Sulfate and chloride concentrations are expressed in mg/kg on a dry weight basis.

Sample Number	Description	pH	Chloride (mg/kg)	Sulfate (mg/kg)	Resistivity (Ohms-cm)
B-1 @ 0'-5'	CLAYEY SAND	8.07	10.33	12.60	14,925
B-2 @ 0'-5'	SILTY SAND	8.52	16.10	76.68	7,299

The soluble sulfate content is less than 1000 mg/kg, which is *negligible* according to ACI 318 (*S0* exposure category), and therefore special considerations for concrete which will be in contact with the onsite soils are *not* required. The corrosivity data should be provided to the project team, AGS does not practice in the field of corrosivity engineering.

3.5 Groundwater

At the time of our field exploration, groundwater was not encountered in any of the borings or test pits, which were excavated to a maximum depth of approximately 40.5 feet below the existing ground surface, where auger refusal was encountered. Based on the enclosed Figure 5, *Depth to Historically High Groundwater Map* (CGS, 2002), the historically highest groundwater level below the subject site ranges from approximately 17 to 18 feet below the existing ground surface at the extreme west end of the site, to deeper than 40 feet below the existing ground surface within the entire eastern half of the site.

Groundwater elevations are dependent on seasonal precipitation, irrigation, land use, and climatic conditions, among other factors, and as a result fluctuate. Therefore, water levels at the time of construction and during the life of the structures may vary from the observations or conditions at the time of our field exploration.

3.6 Field Infiltration Testing

Test Pits P-1 through P-4 were each excavated to a depth of approximately 4 feet below the existing ground surface using a backhoe, in the currently proposed stormwater infiltration area, and also in three possible alternate areas, as provided to our office by Jensen Design and Survey. The approximate locations of the test pits are indicated on the *Existing Site Plan* included as Plate 1, the *Topographic Site Plan* included as Plate 2, and *Proposed Site Plan* included as Plate 3. An approximately 12-inch square by 12-inch deep infiltration test hole was then excavated in the bottom of each test pit utilizing a shovel and other hand operated equipment.

The test holes were then pre-saturated starting 24-hours prior to the beginning of the infiltration testing. At the conclusion of the pre-saturation period, infiltration testing was performed by filling each infiltration test hole with water to approximately 12 inches above the bottom, and recording the drop of the water surface at 30-minute time intervals for a period of 4 hours. The test results are included on the attached Figures 8 and 9.

A summary of the field and corrected infiltration test results is presented in the following table, along with the appropriate correction factors and corrected rates, based on the correction factors for a 12"x12"x12" infiltration test hole, as specified in L.A. County document GS200.2 (2017). The slowest infiltration rate obtained in each test hole was utilized in these calculations:

Test Hole	Stabilized Field Infiltration Rate (minutes/inch)	Stabilized Field Infiltration Rate (inches/hour)	Correction Factor, Per LA County Document GS200.2	Corrected Infiltration Rate (minutes/inch)	Corrected Infiltration Rate (inches/hour)
P-1	21.82	2.75	2.47	53.9	1.11
P-2	14.12	4.25	2.31	32.6	1.84
P-3	8.57	7.00	2.00	17.1	3.50
P-4	8.00	7.50	1.94	15.6	3.86

No grading or compaction should be performed in the area of the proposed infiltration features, *at or near the depth of infiltration*. If any grading is conducted in the infiltration areas which causes compaction, the bottom of

infiltration features should be deepened below any compacted soils, and into undisturbed and uncompacted native soils. It is recommended that infiltration basins be excavated down to the proposed depth of infiltration utilizing an excavator staged *outside the basin*, at least within 2 to 3 feet of the infiltration depth.

A more detailed discussion of, and recommendations for the construction of the currently proposed and alternate infiltration basins is provided in the *Proposed Stormwater Management and Infiltration* section of this report.

4. SEISMICITY

4.1 Seismic Design Criteria

The seismic design of structures based on the 2019 California Building Code (CBC) utilizes the *Maximum Considered Earthquake Ground Motion*. This ground motion and the associated spectral response accelerations are then adjusted for the general type of earth materials within approximately the upper 100 feet underlying the site, termed a *Site Class*. The *Site Class* is based on parameters such as shear wave velocity, standard penetration test resistance, undrained shear strength, and earth material type. For the subject site, which is underlain by deep younger alluvium, the *Site Class* would be 'D', which corresponds to a *stiff soil*.

The site-specific seismic design criteria required by the 2019 CBC were determined utilizing the SEAOC/OSHPD (2022) Seismic Design Maps online web app, utilizing the most current, ASCE 7-16 Standard. The complete output from this web app is attached, and the primary design parameters are summarized in the table below. The *Site Class* option of '*D – Stiff Soil*' was utilized in the analysis.

ASCE Standard	Site Class	F_a	F_v	PGA	PGA_M	S_S	S_1	S_{MS}	S_{M1}	S_{DS}	S_{D1}
7-16	D	1.0	Null*	1.1	1.022	2.108	0.794	2.108	Null*	1.406	Null*

*** See Section 11.4.8 of ASCE 7-16**

Conformance to these criteria does *not* constitute a guarantee or assurance that significant structural damage will *not* occur if a maximum level earthquake occurs. The primary goal of seismic design is to protect life and *not* to avoid all damage, since such design may be economically prohibitive.

4.2 Earthquake Effects

The intensity of ground shaking during an earthquake can result in a number of phenomena classified as ground failure, which include ground rupture due to faulting, landslides, liquefaction, and seismically induced settlement. Other seismic hazards include seiches and tsunamis. Descriptions of each of these phenomena and an assessment of each, as it may affect the subject site, are included in the following sections. The Seismic Hazards Mapping Act of 1990, which became effective in 1991, requires mitigation of seismic hazards to a level that does *not* cause collapse of a building intended for human occupancy, but it does *not* require mitigation to a level of no ground failure or structural damage.

4.2.1 Shallow Ground Rupture

Ground surface rupture occurs when movement along a fault is sufficient to cause a gap or rupture where the upper edge of the fault zone intersects the ground surface. Such ruptures rarely occur as single breaks or are confined to a narrow zone. More commonly, ground rupture associated with faulting is characterized by relatively short segments of faulting that occur over a broad area of the upper plate. In some cases, particularly in unconsolidated alluvial sediments, *secondary ground ruptures* can develop from a number of causes not necessarily related directly to surface rupture of the causative fault. The secondary ground ruptures may be caused by ground shaking, seismic settlement, landslides, and liquefaction.

Since there are *no* known active or potentially active faults passing through the site, the potential for on-site ground rupture due to movement on an underlying fault in *not* considered a significant hazard, although it is a possibility at any site. The potential for ground rupture due to other causes is discussed in the following sections.

4.2.2 Earthquake-Induced Landsliding

Earthquake-induced landslides are slope failures that occur where the horizontal seismic forces act to induce soil failure. Seismic Hazard Maps have been released by the California Geological Survey that delineate areas that have been subject to, or are potentially subject to landsliding as a result of earthquake-induced ground shaking. The majority of the subject site and surrounding area are relatively flat to only gently sloping, and therefore earthquake-induced landsliding is these areas is *not* considered to be a hazard within the majority of the site.

As shown on the *Earthquake Faults and Seismic Hazard Zones Map* (CGS 2003) included as Figure 4 of this report, the offsite slope which ascends to the east of the subject site has been identified as being potentially susceptible to earthquake induced landslide activity.

Furthermore, as detailed in previous sections of this report, our review of historical aerial photographs and our onsite reconnaissance and exploration programs have indicated that pre-historic landslide activity has impacted the easternmost portion of the site, and the existing east ascending slope which ascends offsite beyond the eastern property line. The surficial expression of the landslide feature indicates that movement has not occurred within historic time, and the interpreted interfingering of the landslide deposits with the older alluvium present below the western portion of the site indicate that the landslide activity was not recent.

Due to the presence of fencing near the base of the landslide feature, and the presence of dense vegetation and over-steepened slope faces within the landslide feature, additional exploration within this landslide feature was not feasible at the time of our exploration program. Regional mapping as published by Dibblee (1988) and the USGS (2003), and a measurement taken in an outcropping at the base of the slope, north of Test Pit TP-3, indicate that bedding is favorable with respect to the existing slope geometry, as detailed on *Cross-Section B-B'* included in Plate 4 of this report. Based upon the bedding attitude recorded in Test Pit TP-2, a slight out of slope component of bedding has been indicated on *Cross-Section A-A'*, also included on Plate 4 of this report.

Although the currently proposed development plans, as included as the base map for the *Proposed Site Plan* included as Plate 3 of this report, indicate that grading will be performed and buildings constructed near the base of the east ascending slope, within the area impacted by the existing landslide debris, as detailed elsewhere within this report, it is our recommendation that the proposed development plan be modified to exclude the currently proposed grading, and to remove and/or relocate the three proposed structures within this portion of the site. As a result of these recommended changes, it is our professional opinion that the risk of earthquake induced landsliding impacting the proposed improvements should be considered to be low.

4.2.3 Seiches and Tsunamis

Seiches are an oscillation of the surface of an inland body of water that varies in period from a few minutes to several hours. Seismic ground shaking can induce such oscillations. Tsunamis are large sea waves produced by submarine earthquakes or volcanic eruptions. The site is *not* located close to, or downstream of an inland body of water, and is at an elevation sufficiently above sea level to be outside the zone of a tsunami runup, and therefore the risk of these two hazards is *not* considered pertinent to this site.

4.2.4 Evaluation of Liquefaction Potential

The subject site is *not* located in an area designated as being potentially liquefiable on the State of California Seismic Hazard Zones Map of the Ventura Quadrangle (CGS, 2003), as shown on the attached Figure 4, *Earthquake Fault and Seismic Hazard Zones Map* (potentially liquefiable areas are indicated by the green shading on this map). Therefore, liquefaction is not considered to be a hazard to the subject site, and liquefaction analysis is not required.

4.2.5 Dynamic Dry Settlement

Dynamic dry settlement is the consolidation of relatively loose sandy soils as a result of seismic shaking. The upper site soils will be over-excavated and recompacted, and the underlying earth materials consist of dense to very dense or stiff older alluvial deposits, which would not be considered subject to any measurable dynamic dry settlement due to seismic shaking. Therefore, dynamic dry settlement would not be considered to be a hazard to the subject site.

5. CONCLUSIONS AND RECOMMENDATIONS

5.1 Conclusions and Design Requirements

Based on the findings of our data review, subsurface exploration, laboratory testing, field testing, and engineering analysis, and within the scope of this study, it is the opinion of AGS that construction of the proposed farmworker housing development is *feasible* from a geotechnical engineering viewpoint, with some modifications to the proposed scope and plans that were provided to our office, as discussed herein. The recommendations contained within this report should be incorporated into the project design, and implemented during construction.

5.1.1 Faults / Seismicity

Although there are no known active or potentially active surface fault traces on the subject site, like most of Southern California, the site lies within a seismically active area. Earthquake resistant structural design is recommended, and is required by the building code. Designing structures to be earthquake-proof is generally considered to be impractical, especially for private projects, due to cost limitations. Significant damage to structures may be unavoidable during large earthquakes. Structural design based on the 2019 CBC (California Building Code) structural analysis procedures specifies the use of the seismic parameters given previously in the *Seismic Design Criteria* section. These minimum code values are intended to protect life and may not provide an acceptable level of protection against significant cosmetic damage and serious economic loss. Significantly higher than code parameter values may be necessary to further reduce potential economic loss during a major seismic event.

5.1.2 Hazardous Materials

AGS has *not* been retained to provide any type of environmental assessment of the subject property, *nor* to provide recommendations with respect to any contamination that might be present. AGS does not practice in the field of environmental assessment.

5.1.3 Cut Slopes

Proposed cut slopes are shown at the east end of the site, as indicated on the *Proposed Site Plan* included as Plate 3 of this report. However, as discussed herein, it is recommended that no cuts be made into the existing slope at the east end of the site. No other cut slopes have been proposed elsewhere on the site.

5.1.4 Fill Slopes

Fill slopes are proposed to be constructed on portions of the site as part of the planned development. Fill slopes will be a maximum 2:1 (horizontal:vertical) in gradient, with maximum anticipated heights of approximately 10 vertical feet. The fill slopes should be constructed in accordance with the recommendations presented in the *Site Preparation* section of this report.

5.1.5 Rockfall

Damage to life or property due to rockfall as a result of the construction of the proposed improvements is *not* considered to be a risk at the subject site.

5.1.6 Slope Setback

When located next to a descending 3(H):1(V) slope or steeper, the base of footings for buildings should be a minimum of 5 feet or one-third (⅓) the slope height from the face of slope, whichever is greater, but need *not* exceed 40 feet from the face of slope. When located next to an ascending 3(H):1(V) slope or steeper, the base of footings

for structures should be a minimum of 3 feet, or one-half (½) the slope height from the toe of slope, whichever is greater, but need *not* exceed 15 feet from the toe of slope. *Examples of Slope Setbacks* are included on the attached Figure 6.

5.1.7 Offsite Drainage

Berms should be established at the tops of descending slopes, to divert drainage and prevent it from concentrating and flowing over slope faces, or offsite.

5.1.8 Proposed Stormwater Management and Infiltration

The current plan shows a large detention and infiltration basin near the west end of the site, as shown on the attached Plate 3 of this report. The bottom of this basin as shown on the current plan will require the placement of approximately 4.25 to 8.25 feet of fill above the current existing site grade, and the construction of fill slopes up to a maximum of approximately 10 feet in height overall, and 3 feet above the bottom of the basin, to create the sloping sides of the basin. A primarily granular, permeable compacted fill would have to be imported to create the bottom of this basin, between the depth of initial over-excavation and the finished grade in the bottom of the basin, and it may be difficult and/or costly to find such a large volume of consistent, select granular fill for this purpose. In addition, very extensive, ongoing testing would be required by the Geotechnical Engineer during the import and placement of this material, to verify the consistency, and minimum required permeability.

It's our understanding that the current plan is somewhat preliminary, and if this basin is to be constructed as shown on the attached Plate 2, it would be recommended that the upper 4 feet approximately of existing native soils first be over-excavated and removed, prior to placing the select, primarily granular fill, and relatively permeable compacted fill. It is also recommended that the contact between the imported primarily granular fill and underlying native soils be relatively level. Note that the imported granular material *would* still require the typical minimum 90% relative compaction, in order to maintain the stability of this basin and adjacent slopes, and therefore this material, *when compacted*, will have to be at least as permeable as the underlying native soils. It would also be recommended that the sloping sides within the interior of the basin be lined with an impermeable liner, to at least reduce the migration of the detained water towards the descending perimeter slopes, and also to prevent erosion of the interior slopes. It is recommended that the liner also extend vertically downward from the toe of the interior descending slopes, to the bottom of the permeable import material (the contact with undisturbed native soils), in order to prevent or at least reduce horizontal migration of the detained water towards the exterior slope faces, and reduce the potential for the infiltrated water to daylight in the lower surrounding areas to the north and west of the basin. Another requirement for the descending slopes around the perimeter of this proposed detention/infiltration basin would be that the earth materials utilized to construct these slopes be relatively cohesive, and that a minimum 95% compaction be achieved.

Possible alternative infiltration locations which are already being considered by the Project Civil Engineer would be to construct typical underground infiltration basin(s) within either or both of the two large centralized proposed landscaped courtyard areas, and/or within the proposed parking area at the southwest corner of the site. Infiltration testing was conducted within these three areas as part of this study (P-1 and P-2 are within the proposed landscaped courtyard areas, and P-4 is within the proposed southwest parking area), as well as within the currently proposed large detention/infiltration basin shown on the current plan, Plate 3 of this report (P-3 was in this area). If any of these alternative underground infiltration basin(s) are constructed, it is also recommended that a minimum of the upper 4 feet of existing native soils first be over-excavated and removed, prior to placing the first layer of infiltration system gravel within the basin(s). The bottom of these basin areas should be relatively level, prior to placing the first layer of gravel.

The intentional introduction of enormous amounts of water into the ground via the infiltration of onsite stormwater is a relatively new concept, and is inherently risky, regardless of any precautions which may be taken. Infiltration is especially risky when conducted below paved parking areas or other miscellaneous improvements, and should preferably be done below landscape areas only, and should be as far as possible from the proposed structures,

pavements, site walls, sidewalks and other improvements. Some potential settlement and cracking of any improvements located directly above, or in the vicinity of infiltration features may be possible. There should also be careful coordination of the site utility locations with any proposed stormwater infiltration features. The proposed stormwater infiltration features should *not* be allowed to come into contact with, or to even be in close proximity to utility trench backfill, and utilities are not allowed to cross above, below or through any proposed infiltration features, with the exception of irrigation lines within landscape areas entirely above infiltration areas.

5.1.9 Site Drainage

All surface runoff must be carefully controlled, and must remain a crucial element of site maintenance. Proper drainage and irrigation are important to reduce the potential for excessive infiltration adjacent to foundations, pavements, and other miscellaneous improvements. Final grading should provide positive drainage away from the proposed structures and other improvements. All pad drainage shall be collected and diverted away from proposed buildings and foundations in non-erosive devices. All drainage piping should be watertight and discharge to an appropriate location, as determined by the Project Civil Engineer.

All underground plumbing fixtures should be absolutely leak-free. As part of the maintenance program, utility lines should be checked for leaks for early detection of water infiltrating the soils that could cause detrimental soil movements. Detected leaks should be promptly repaired. Proper drainage shall also be provided away from the building footings during construction. This is especially important when construction takes place during the rainy season.

Seepage of surface irrigation water or the spread of extensive root systems into the subgrade of footings, slabs, concrete flatwork or pavements can cause differential movements and consequent distress in these structural elements. Trees and large shrubbery should *not* be planted so that roots grow under foundations and flatwork when they reach maturity. Landscaping and watering schedules should be planned with consideration for these potential problems.

Drainage systems should be well maintained, and care should be taken to *not over* or *under* irrigate the site. Landscape watering should be held to a minimum while maintaining a uniformly moist condition without allowing the soil to dry out. During extreme hot and dry periods, adequate watering may be necessary to keep soil from separating or pulling back from the foundations. Cracks in paved surfaces should be sealed to limit infiltration of surface waters.

5.1.10 Plan Review

When final Grading and Structural Plans become available, they should be reviewed by AGS *prior* to submittal to regulatory agencies for approval. Additional analysis *may* be required at that time depending on specific details of the proposed grading and improvements. Approval by this office will be indicated on the plans by either manual or digital signature and stamp.

5.1.11 Additional Recommendations

The following additional geotechnical recommendations should be incorporated into the final design, and construction plans. All such work and design should be in conformance with applicable governmental regulations or the recommendations contained herein, whichever are more restrictive. The following recommendations have *not* been reviewed or approved by any governing agency at this time. These recommendations may change based on obtaining approval from the County. Design of the proposed project should be made following approval from the County.

5.2 Site Preparation

General guidelines are presented below to provide a basis for quality control during site grading. It is recommended that all compacted fills be placed and compacted with engineering control under continuous observation and testing by a field representative of the Geotechnical Engineer, and in accordance with the following requirements.

5.2.1 Removals

a. When demolishing any existing improvements on the site, the contractor should locate any existing foundations, floor slabs, debris pits, existing fill, and subsurface trash which may be present. These soils and structures should be completely removed. In the area of the proposed structures and other improvements, deeper removals may be required, as discussed below.

b. Remove all vegetation and loose soil *prior* to fill placement. The general depth of stripping should be sufficiently deep to remove any root systems, and the upper relatively porous soils. Based on our subsurface exploration across the site, the thickness of the upper relatively porous soil requiring removal is anticipated to be approximately 2 to 3 feet, but for uniformity, the depth of initial over-excavation should be an overall minimum depth of 3 feet below the existing site grade. In addition, a careful search shall be made for subsurface trash, abandoned masonry, abandoned tanks and septic systems, and other debris during grading. All such materials shall be removed *prior* to fill placement. The removal of trees and large shrubs should include complete removal of their root structures.

c. In the area of the proposed structures, and throughout the entire site where the existing grade will be raised by the placement of additional fill, any existing artificial fill, disturbed soils and the upper relatively porous soils should be over-excavated and recompacted. For uniformity, it is recommended that this initial depth of over-excavation extend to a minimum of 3 feet below the existing site grade, and 3 feet below the bottom of the proposed building and retaining wall foundations, whichever is deeper. In addition, all building and retaining wall foundations should be underlain by a relatively uniform blanket of newly placed compacted fill, where the ratio of the maximum to minimum depths of compacted fill below bottom of footing does not exceed approximately 2.5:1.

d. In proposed street, parking, driveway, and other flatwork areas (patios, walkways, etc.), and any other areas of miscellaneous surface improvements, and where the existing grade is to be raised by the placement of fill, any existing artificial fill, disturbed soils, and upper relatively porous soils should be over-excavated and recompacted. In order to provide more uniform support for the proposed fill and overlying improvements, the depth of initial over-excavation should extend to a minimum of 3 feet below existing and future site grade, and a minimum of 12 inches below bottom of improvements or pavement structural section, whichever is deeper.

e. The lateral limits of initial over-excavation can be limited to the areas of the proposed structures, retaining walls, pavement, and other miscellaneous improvements, and areas where the grade will be raised by the placement of additional compacted fill, but should extend a distance of at least 5 feet beyond the outside perimeter of all building and retaining wall foundations where possible, or for a distance equal to the depth of compacted fill, whichever is greater. The lateral limits of over-excavation should extend a minimum distance of at least 2 feet beyond the outside perimeter of pavement areas and other surface improvements, where possible, or for a distance equal to the depth of compacted fill, whichever is greater. A careful search shall be made for deeper areas of loose soil during grading operations. If encountered, loose areas should be properly removed to the firm underlying native soil and properly compacted.

5.2.2 Bottom Stabilization

a. Depending on the time of year, amount and recency of precipitation, and the type and size of equipment utilized during grading, stabilization of the bottom of over-excavation may be required. If the bottom is found to be 'pumping' due to excessive moisture, stabilization may be required in order to allow the placement and proper compaction of fill. At the time of our

field exploration, which was conducted during a prolonged period of relatively dry weather, the upper earth materials in the areas explored had moisture contents in a range not likely to cause pumping at the depth of over-excavation. However, the soils may have increased moisture content directly below the existing trees, in the areas of the currently active orchard drip irrigation system, and/or during winter.

b. It's our recommendation that bottom stabilization, if and where required, consist of alternating layers of Tensar *InterAx* Geogrid and aggregate base. Using this method, the required over-excavation should still first be made to a minimum depth of 3 feet below the existing and future grade level, and a minimum of 3 feet below bottom of the proposed building foundations, whichever is deeper. It is recommended that a large excavator staged outside the excavation be utilized for the initial over-excavation in any areas of pumping soils. The first layer of geogrid should then be placed directly on a relatively level, native soil bottom of over-excavation. Adjacent layers of geogrid should be overlapped a minimum of 18 inches.

c. Some type of imported aggregate base material, which may include recycled AC/PCC/AB should then be placed over the geogrid in two approximately 6-inch thick compacted layers (about 8 to 9-inch +/- loose lifts), for a total of 12 inches of compacted base, compacted to a minimum 90% compaction. The imported 'base-like' material does not have to meet exact road base specifications, but should have very minimal fines content, similar to base. The intent of recommending this general type of material is that it compacts more easily than a typical soil with more fines content, thereby reducing potential disturbance to the underlying subgrade, and increasing the ease of compaction. This type of material is also less prone to absorb excessive moisture from the very moist subgrade soils that would underlie the geogrid in any areas needing stabilization, and a generally granular type of material is required for interlock with the geogrid, in order to mobilize the functionality of the geogrid.

d. It is recommended that the base be properly moisture conditioned and thoroughly mixed *outside* the excavation, and prior to placement over the geogrid. It is also recommended that an excavator staged outside the excavation, or small track-mounted equipment, be utilized to spread the base over the geogrid. Wheel-mounted equipment and dynamic compaction methods would not be recommended for compaction over pumping soils.

e. If sufficient stabilization has not yet been achieved to allow the placement and compaction of onsite soils over the top of the first 1-foot of geogrid and compacted base, then another layer of geogrid should be placed on top of the base, followed by a 6-inch layer of compacted base. Again, if sufficient stabilization has not yet been achieved, another 6-inch layer of compacted base should be placed, and stabilization tested again. If stabilization has not been achieved by this time, the use of smaller and/or track-mounted equipment should be considered for use within the excavation. If necessary, another layer of geogrid could be placed, followed by another 6-inch layer of compacted base.

5.2.3 Suitable Fill Material

a. The excavated onsite soils, cleaned of deleterious material, can be re-used for fill, but should be moisture conditioned (i.e., by drying, or adding water, as necessary), and thoroughly mixed. Rock larger than 6 inches should *not* be buried or placed in compacted fill. Rock fragments less than 6 inches may be used provided the fragments are *not* placed in concentrated pockets, and a sufficient percentage of finer grained material surrounds and infiltrates the rock voids.

b. Imported material should generally have engineering properties similar to, or more favorable that those on the subject site, and it is also recommended that any import material have an

expansion index of less than 50, and an R-value of at least 15. Imported material will require testing to verify the engineering properties, and must be approved by the Geotechnical Engineer *prior* to placement on the site.

5.2.4 *Placement of Compacted Fill*

a. All fill materials should be placed in controlled, horizontal layers *not* exceeding 6 to 8 inches in loose thickness, and moisture conditioned to a minimum of approximately 2% over optimum moisture content, but no more than approximately 5% over optimum, and *thoroughly* mixed. This recommendation for minimum moisture content is based on the expansiveness of the upper onsite soil, and could be reduced for soils with much lesser expansion potential, but it is recommended that all earth materials, including aggregate base, be moisture conditioned to at least optimum moisture content, prior to compaction.

b. Fill materials should be compacted to a minimum 90% of the laboratory maximum dry density (95% for the upper 12 inches in areas subject to vehicular traffic, and for the slopes around the proposed detention/infiltration basin), as determined by ASTM D1557. If either the relative compaction or moisture content do *not* meet these criteria, the contractor should rework the fill until it does meet the criteria. If the fill materials pump (flex) under the weight of construction equipment, difficulties in obtaining the required minimum compaction may be experienced. Therefore, if soil pumping occurs, it may be necessary to control the moisture content to a closer tolerance (e.g., 2 to 3% above optimum), use construction equipment that is not as prone to cause pumping, or implement the stabilization methods discussed previously in this report.

c. The field test methods to be used to determine the in-place dry density of the compacted fill shall be in conformance with either ASTM D1556 (sand cone test method) or ASTM D2922 (nuclear gauge method).

d. Subgrade to be utilized for the support of any exterior surface improvements shall be moisture conditioned, as required, to at least approximately 2% over optimum moisture content, but no more than approximately 5% over optimum, thoroughly mixed, and be recompacted to at least 90% of the maximum dry density to a depth of at least 12 inches (95% for the upper 12 inches in areas subject to vehicular traffic). This recommendation for minimum moisture content is based on the expansiveness of the onsite soil, and could be reduced for soils with lesser expansion potential, but it is recommended that all earth materials, including aggregate base, be moisture conditioned to at least optimum moisture content.

5.2.5 *Fill Slopes*

a. Fill slopes must be founded on a keyway of undisturbed, competent native material approved by the Geotechnical Engineer or Geologist, and/or their field representative. The keyway should be a minimum of 10 feet in width, dipped into the retained side, must extend at least to the proposed toe of slope, and extend at least 3 feet into competent native material at the outer edge of the keyway. The fill slope should be benched into competent, native material.

b. Fill slopes shall be constructed by placing fill soil to a sufficient distance beyond the proposed finished slope surface to allow compaction equipment to operate at the outer surface limits of the final slope surface, and then cutting back to finished grade. Other suitable methods of properly compacting the slope surface would be allowed along property lines.

5.2.6 *Testing of Compacted Fill*

a. At least one compaction test shall be performed for every 500 yd^3 of the fill material. In addition, at least one test shall be performed for every 2 feet of fill thickness.

5.2.7 Detention/Infiltration Basins

a. If the large detention/infiltration basin shown near the west end of the site is to be constructed as shown on the attached Plate 2 of this report, a minimum of approximately the upper 4 feet of existing native soils should first be over-excavated and removed, prior to placing select, primarily granular, and relatively permeable compacted fill for the bottom of the basin. It is also recommended that the contact between the bottom of the imported primarily granular fill and underlying native soils be relatively level.

b. The select imported primarily granular basin bottom fill material *would* still require the typical minimum 90% relative compaction, in order to maintain the stability of this basin and adjacent slopes, and therefore this material, *when compacted*, will have to be at least as permeable as the underlying native soils, by extensive testing throughout the placement of this fill.

c. The sloping sides within the interior of the basin should be lined with an impermeable liner, to prevent the migration of the detained water towards the descending perimeter slopes, and also to prevent erosion of the interior slopes. The liner should also extend vertically downward from the toe of the interior descending slopes, to the bottom of the permeable import material (the contact with undisturbed native soils), in order to prevent or at least reduce horizontal migration of the detained water towards the exterior slope faces, and reduce the potential that infiltrated water would daylight in the lower surrounding areas to the north and west of the basin. The descending slopes around the perimeter of this proposed detention/infiltration basin should be compacted to a minimum 95% relative compaction, and the earth materials utilized to construct these slopes be relatively cohesive.

d. If any of the three alternative infiltration basin(s) are to be constructed, it is recommended that the upper 4 feet of existing native soils in these areas first be over-excavated and removed, prior to placing the first layer of infiltration system gravel within the basin(s). The bottom of these basin(s) should be relatively level, prior to placing the first layer of gravel. Additional gravel may be utilized as necessary to fill up to the bottom of proposed infiltration chambers.

5.2.8 Inclement Weather and Construction Delays

a. If construction delays or the weather result in the surface of the fill drying, the surface should be scarified, moisture conditioned and recompacted before the next layer of fill is added. Each new layer of fill should be placed on a rough surface so planes of weakness are not created in the fill.

b. During periods of wet weather and before stopping work, all loose material shall be spread and compacted, surfaces shall be sloped to drain to areas where water can be removed, and erosion protection or drainage provisions shall be made in accordance with the plans provided by the Civil Engineer. After the rainy period, a field representative of the Geotechnical Engineer shall *review* the site for authorization to resume grading, and to provide any specific recommendations that may be required. As a minimum, however, surface materials previously compacted before the wet weather shall be scarified, brought to the proper moisture content, and recompacted *prior* to placing additional fill.

c. During the construction of foundations, floor slabs and any exterior concrete flatwork, construction sequences should be scheduled to reduce the time interval between subgrade preparation and concrete placement to avoid drying and cracking of the subgrade, or the surface should be covered or periodically wetted to prevent drying and cracking.

5.2.9 Responsibilities

a. Representative samples of material to be used as compacted fill should be analyzed in the laboratory by the Geotechnical Engineer to determine the physical properties of the materials. If any materials other than those previously tested are encountered during grading, the appropriate analysis of this material should be conducted by the Geotechnical Engineer as soon as practicable. Any imported soil from off-site sources shall be approved *prior* to placement.

b. All grading work shall be observed and tested by the Project Geotechnical Engineer or their field representative to confirm proper site preparation, excavation, scarification, and compaction of onsite soil, selection of satisfactory fill materials, and placement and compaction of fill. All removal areas and footing excavations shall be observed by the field representative of the Project Geotechnical Engineer before any fill or steel is placed.

c. The lateral limits and the depths of the required over-excavation and recompaction should be shown by the Civil Engineer on the grading plans.

d. The grading contractor has the ultimate responsibility to achieve uniform compaction in accordance with the geotechnical report and grading specifications.

5.3 Utility Trench Backfill

The onsite soils are suitable for backfill of utility trenches from 1-foot above the top of the pipe to the surface, provided the material is free of organic matter and deleterious substances. The existing site soils should provide a firm foundation for site utilities, but any soft or unstable material encountered at pipe invert should be removed and replaced with an adequate bedding material.

The site Civil Engineer in accordance with manufacturer's requirements should specify the type of bedding materials. Granular soils should be imported for bedding and shading of utilities. Jetting of bedding materials should *not* be permitted unless appropriate drainage is provided and the bedding has a sand equivalent greater than 50.

Trench backfill should be placed in 6 to 8-inch lifts, and properly moisture conditioned and compacted in accordance with the recommendations provided in the *Site Preparation* section of this report. Jetting of trench backfill is *not* acceptable to compact the backfill.

Major underground utilities shall *not* cross beneath buildings unless specifically approved by the Project Civil Engineer and respective utility company. If approved, trenches crossing building areas shall be backfilled with a select gravelly sand compacted to 95% relative compaction.

5.4 Temporary Excavations

It is anticipated that most temporary excavations may be made to a maximum vertical height of 5 feet, however any sands which may be encountered should be excavated at a uniform 1.5:1 gradient. Excavations greater than 5 feet in height should be sloped back at either a uniform 1:1 gradient for cohesive soils, and 1.5:1 for sands. Excavations should *not* be allowed to become soaked with water or to dry out. Surcharge loads should *not* be permitted within a horizontal distance equal to the height of the excavation from the top of the excavation, unless the excavation is properly shored. Excavations that might extend below an imaginary plane inclined at 45 degrees below the edge of an existing foundation should be properly shored to maintain foundation support for the existing structure. All temporary excavation should be observed by a representative of the Geotechnical Engineer during excavation, to verify the anticipated soil conditions.

5.5 Foundation Design

After the over-excavation and recompaction of the existing upper site soils, and the import and placement of additional compacted fill to achieve the future finished grades across the site, conventional shallow footings founded entirely within certified compacted fill can be utilized for foundation support for the proposed multi-family structures, and retaining walls. All foundations for these structures should be underlain by a minimum of 3 feet of compacted fill. Free-standing site walls not exceeding approximately 6 feet in height may bear in either compacted fill, or undisturbed, competent native soils, although any given length of wall should bear entirely within one material. The following design criteria may be used in the design of conventional, shallow footings.

5.5.1 Minimum Footing Dimensions

Minimum Footing Embedment Depth (inches)	Minimum Continuous Footing Width (inches)	Minimum Isolated or Pad Footing Width, (inches)
1 or 2-Story - 21 3-Story - 24	1-Story – 12 2-Story – 15 3-Story - 18	24

Where located adjacent to utility trenches, footings shall extend below a 1:1 plane projected upward from the inside bottom of the trench. Note that these foundation depths are based on the expansiveness of the upper onsite soils. If less expansive soils are placed *throughout* the upper 4 feet of any given building pad, retaining wall area, or other miscellaneous footing areas, these values could be reduced, but should still comply with the minimum depths provided in Ventura County Building and Safety Standard B-49, Table 1805.4.2.

5.5.2 Allowable Bearing Pressure and Lateral Resistance

Allowable net vertical soil bearing pressure, including dead and live loads, are given below for footings founded on compacted fill at the minimum required embedment depths, provided the footing width equals or exceeds the recommended minimum.

Structure Type	Bearing Material	Allowable Bearing Pressure (psf)	Allowable Sliding Friction Coefficient	Allowable Passive Resistance (psf/ft of depth)	Maximum Passive Resistance (psf)
BUILDINGS & RETAINING WALLS	COMPACTED FILL	2500	0.3	250	2500
FREE-STANDING SITE WALLS <~6'	COMPETENT NATIVE SOILS	1000	0.2	150	1500

The bearing capacity can be increased by ⅓ when considering short duration wind or seismic loads. Resistance to lateral loads can be assumed to be provided by friction along the base of the foundation, and by passive earth pressure on the side of the footing. The allowable friction coefficient may be used with the vertical dead loads, and the allowable lateral passive pressure can be utilized for the sides of footings poured against the recommended bearing material. These allowable values can be increased by a factor of 1.5 to convert from allowable to ultimate values. It is recommended that the upper 1-foot of soil be neglected when computing lateral resistance, due to the potential for the material to become disturbed or degraded during the life of the structure.

5.5.3 Foundation Settlement

Static settlement of proposed foundations due to dead and frequently applied live loads is not expected to exceed approximately ½ to ¾-inch under the assumed loading conditions, and is expected to occur primarily upon initial application of loading. Differential settlement is not expected to exceed approximately ¼ to ½-inch.

5.5.4 Steel Reinforcement

All continuous foundations should be reinforced with a minimum of four #4 steel bars. Two of these should be placed near the top of the foundation, and two should be placed near the bottom. Final structural details of the

footings, such as footing thickness, concrete strength, and amount of reinforcement, should be determined by the project Structural Engineer, but should comply with the above minimums. The earth materials underlying the subject site are in the *low to medium* expansion range. Expansion index tests should be performed at the time of grading, to determine the final expansion index of the graded pads.

5.5.5 Required Observations

Prior to placing concrete in the footing excavations, an observation should be made by the field representative of the Geotechnical Engineer, to confirm that the footing excavations are free of loose and disturbed soils, and are embedded in the recommended earth materials.

5.6 Floor Slab Design

It is recommended that concrete slabs-on-grade be a minimum of 4 inches thick, and be reinforced with a minimum of #4 steel bars placed a minimum of 18 inches on center each way. The exact structural details such as slab thickness, concrete strength, reinforcement, and joint spacing, should be determined by the project Structural Engineer, but should comply with these minimum requirements. Additional expansion index testing should be performed at the time of grading to confirm the expansion index of the final graded pads.

Cracking of concrete flatwork can occur and is relatively common. Steel reinforcement and crack control joints are intended to reduce the risk of concrete slab cracking, as are the use of proper concrete curing, and sometimes fiber reinforced concrete. Also, concrete slabs are generally not perfectly level, but they should be within tolerances included in the project specifications.

Tile flooring can crack, reflecting cracks in the underlying concrete slab. Therefore, if tile flooring is used, the slab designer should consider additional steel reinforcement, above minimum requirements, in the design of concrete slabs-on-grade where tile will be installed. Furthermore, the tile installer should consider installation methods, such as using a vinyl crack isolation membrane between the tile and concrete slab, to reduce the potential for tile cracking.

If earthwork operations are conducted such that the construction sequence is not continuous, or if construction operations disturb the surface soils, it is recommended that the exposed subgrade to support concrete slabs be tested within a day of the concrete pour or placement of sand (or vapor barrier, where utilized) to verify adequate compaction and moisture conditions. If adequate compaction and moisture conditions are not demonstrated, the disturbed subgrade should be over-excavated, scarified, and recompacted in accordance with the guidelines in the *Site Preparation* section of this report *prior* to the slab being poured, or sand and vapor barrier being placed.

5.6.1 Sand and Vapor Barrier

It is recommended that all building floor slabs be underlain by a *minimum* of 4 inches of sand, based on the expansion index range of the onsite soils, and County of Ventura requirements. If soils in the *very low* expansion range are placed *throughout* the upper 4 feet of any given building pad, 2 inches of sand could be utilized. The thickness of sand should comply with the thickness provided in Ventura County Building and Safety Standard B-49, Table 1805.4.2. It is also recommended that a minimum 15-mil thick plastic vapor barrier be used under floor slabs in moisture sensitive areas. The vapor barrier should be installed in accordance with the recommendations contained in the latest version of ASTM E1643.

The literature is mixed regarding the preferred placement of the vapor barrier with respect to the sand and concrete slab. Some designers prefer to place the vapor directly below the concrete slab, and some prefer to sandwich the vapor barrier between layers of sand. It is our opinion, and the opinion of the *California Geotechnical Engineering Association* that the decision of where to place the vapor barrier does not fall under the responsibility or expertise of the Geotechnical Engineer, and we will therefore defer to the project designer on this matter. Appropriate precautions should be taken whichever placement is chosen.

Seams of the vapor barrier should be overlapped and sealed. Where pipes extend through the vapor barrier, the barrier should be sealed to the pipes. Tears or punctures in the vapor barrier should be completely repaired *prior* to placement of concrete. The concrete mix should be designed so as to minimize possible curling of the slab. The concrete slab should be allowed to cure properly before placing vinyl or other moisture-sensitive floor covering.

5.7 Asphalt and Concrete Pavement

5.7.1 Grading

All exterior areas to be paved with asphalt or concrete should be graded in accordance with the general recommendations for site grading as described in the *Site Preparation* section of this report. In proposed parking and driveway areas, and any other exterior flatwork areas (walkways, patios, etc.), any existing fill material, loose or disturbed soils, and relatively porous upper site soils should be over-excavated and recompacted. The depth of over-excavation should extend to a minimum of 3 feet below the current existing site grade, or 12 inches below future subgrade level, whichever is deeper, and a minimum of 12 inches below the bottom of future concrete, asphalt or aggregate base section. If test results show that proper moisture and compaction requirements do not exist just *prior* to placing base or placing pavements, the surface should be scarified, moisture conditioned, and properly recompacted.

Compaction tests will be required for all asphalt and aggregate base. A minimum relative compaction of 95% is required for all asphalt, aggregate base, and upper 12 inches of subgrade soils. The aggregate base should have a minimum *R*-value of 78 and meet recognized industry specifications for aggregate base. Base materials should be placed and compacted in lifts not exceeding 6 inches. Asphalt should *not* be placed if the base is pumping. Base materials are *not* required beneath curbs and gutters, however, if base materials are not utilized beneath the curbs and gutters, it is recommended that the subgrade soils be recompacted to at least 95% relative compaction to a minimum depth of 12 inches below the bottom of curbs and gutters.

5.7.2 Maintenance

Pavement section design assumes that proper maintenance practices, such as sealing and repair of localized areas of distress, are employed throughout the design life of the pavement.

5.7.3 Asphalt Pavement Design

Pavement section calculations were performed for asphalt pavement design for a range in traffic indices. Selection of the appropriate traffic index to use should be made by the Project Civil Engineer based on their knowledge of traffic flow and loadings.

The structural sections for asphalt pavement were computed in general accordance with the Caltrans method (**California Department of Transportation Highway Design Manual**), using a design R-value of 10, based on the results of R-value testing of a representative sample of the upper onsite soils. The results of the R-value testing are included in Appendix B of this report, and recommended pavement sections are summarized in the following table. Note that the City of Ventura may have overriding minimum pavement sections for public streets.

Traffic Index	Thickness (inches)	
	Asphalt	Aggregate Base
5.0	4.0	6.5
6.0	4.0	10.5
7.0	4.0	12.5

5.7.4 Confirmation of R-Value

Additional representative testing to determine the R-value of the subgrade soils in street, parking and driveway areas, should be performed near or after the completion of grading, in order to finalize the pavement section. It should be noted that the pavement section design recommendations presented in this report may change, depending

on the final composition of the subgrade soils. More favorable pavement sections could be utilized if the upper 2 feet of subgrade soils in proposed asphalt pavement areas are constructed utilizing imported soils with an R-value which is *uniformly* and substantially greater than 10.

5.7.5 Concrete Pavement Design

It is recommended that all concrete pavement subject to vehicular traffic be a minimum of 8 inches thick, and be underlain by a minimum of 6 inches of aggregate base. Concrete flatwork subject only to pedestrian traffic (i.e., sidewalks, walkways, patios, etc.) should be a minimum of 5 inches thick, and need not be underlain by aggregate base. All exterior concrete should be reinforced with a minimum of #4 steel bars placed on 18-inch centers each way. Note that the City of Ventura may have overriding minimum concrete sections and reinforcement for public streets and sidewalks.

It is also recommended that the perimeter of all concrete flatwork and hardscape areas have a reinforced, thickened edge, a minimum of 8 inches wide, and extending a minimum of 8 inches below the bottom of the concrete flatwork, and 12 inches below adjacent grade. The purpose of the thickened edge is to reduce the migration of moisture to or from the area below the slab, thereby reducing the amount of moisture fluctuation below the slab, reducing shrinking and swelling and the consequent movement and distress. The use of permeable pavers or any system of un-grouted bricks or pavers is not recommended, due to the potential for increased water penetration and expansive soil movement. These recommendations could be modified if less expansive soils are imported, and are uniformly present within the upper 2 to 3 feet of final subgrade in any given proposed flatwork or pavement area, depending on the type and use of the pavement/flatwork.

Cracking of exterior concrete and other hardscape can occur and is relatively common. Areas underlain by expansive soils are especially prone to movement and cracking. Steel reinforcement, crack control joints and deepened edges are intended to reduce the risk of concrete cracking, as are the use of fiber reinforced concrete and proper concrete curing. The location and severity of concrete cracking can be controlled and reduced through the use of proper jointing and other construction practices, but can never be completely eliminated.

5.8 Retaining Wall Design Criteria

The following retaining wall design information may be utilized in the design of site retaining walls. Retaining wall foundations may be designed utilizing the criteria provided in the *Foundation Design* section of this report.

5.8.1 Static Lateral Earth Pressures

The earth pressure behind retaining walls depends on the allowable wall movement, type of backfill materials, backfill slopes, surcharges, and hydrostatic pressures if any. The following equivalent fluid pressures are recommended for vertical walls with no hydrostatic pressure, no surcharge, no seismic effects, and a backfill slope with a gradient less (flatter) than 5(H):1(V). Seismic lateral forces would be in addition to the static wall pressures provided below, and would be required for walls retaining more than 6 feet.

	Equivalent Fluid Unit Weight (pcf)			
Wall Movement	Clean Sand or Gravel Backfill (GW, GP, SW, SP)	Silty Sand or Silty Gravel Backfill (SM, GM)	Clayey Sand, Clayey Gravel Backfill (SC, GC)	Silts, Clays (ML, CL)
FREE TO DEFLECT	30	40	45	55
RESTRAINED	40	50	60	80

In areas where the retaining walls retain sloping ground steeper than 5(H):1(V), the equivalent unit weights in the above table should be increased by 13 pcf, for gradients up to the maximum allowable of 2(H):1(V).

These values are applicable for backfill placed between the wall stem and an imaginary plane rising at a 45-degree angle from below the edge (heel) of the wall footing. If the onsite soil is used as backfill within this zone, or is

otherwise present within this zone, the equivalent fluid unit weight associated with a soil classification of ML/CL should be used.

The surcharging effect of anticipated adjacent loads on the wall backfill due to traffic, footings, or other loads, should be included in the wall design. The magnitude of lateral load due to surcharging depends on the magnitude of the surcharge, the size of the surcharge-loaded area, and the distance of the surcharge from the wall. We can provide assistance in evaluating the effects of surcharge loading, if desired, once details are known and provided.

5.8.2 Seismic Lateral Earth Pressures

In accordance with the requirements of the 2019 California Building Code, seismic lateral force should be incorporated into the design of all retaining walls retaining more than 6 feet of earth materials. A seismic lateral force of $15.9H^2$ pounds per lineal foot of wall should be added to *cantilevered* walls retaining more than 6 feet of earth materials and level ground, and a seismic lateral force of 26.6H2 pounds per lineal foot of wall should be added to *cantilevered* walls retaining more than 6 feet of earth materials, and sloping ground up to a maximum 2:1 gradient, where H is the retained height, in feet. A seismic lateral force of $25.8H^2$ pounds per lineal foot of wall should be added to *restrained* walls retaining more than 6 feet of earth materials, and level ground, where H is the retained height, in feet. The seismic force should be applied at a height of 0.4H above the bottom of the wall, and would be in addition to the static lateral earth pressures given in the previous section.

5.8.3 Backfill and Drainage

Except for the upper 18 to 24 inches, the soil immediately adjacent to backfilled retaining walls should be free-draining filter material (such as Caltrans Class 2 permeable material), or gravel wrapped in filter fabric, within a minimum horizontal distance of 1-foot from the back face of the wall. As an alternative to either one of these, a drainage tile product such as Miradrain may be applied to the back face of wall, over the waterproofing. Weep holes and/or a subdrain pipe, as appropriate, should be installed at the base of retaining walls. Subdrain pipe should consist of a minimum 4-inch diameter perforated PVC pipe meeting ASTM D2729 or better, surrounded by a minimum of 1 cubic foot of gravel per lineal foot of pipe, and the entire pipe and gravel system should be wrapped in filter fabric, such as Mirafi 140N. Accordion or similar type pipe is *not* acceptable for subdrain pipe. The top 18 to 24 inches should be backfilled with less permeable compacted fill to reduce infiltration. Figure 7 provides a *Typical Retaining Wall Drainage Detail.*

It is recommended that all retaining walls be properly waterproofed. Advanced Geotechnical Services does not practice in the field of waterproofing design, or the inspection of its application.

During grading and backfilling operations adjacent to any wall, heavy equipment should not be allowed to operate within 5 feet laterally of the wall or within a lateral distance equal to the wall height, whichever is greater, to avoid developing excessive lateral pressures. Within this zone, only hand-operated equipment should be used to compact the backfill soils.

6. OBSERVATIONS AND TESTING

Prior to the start of site preparation and/or construction, *it is recommended that a meeting be held with the Contractor to discuss the project.* We recommend that AGS be retained to perform the following tasks prior to, and/or during construction. Please *advise* AGS a minimum 24 hours *prior* to any required site visit. *All approved plans, permits, and geotechnical reports must be at the jobsite and be made available during inspections.*

a. *Review* grading, foundation, and drainage plans to *verify* that the recommendations contained in this report have been properly interpreted and are incorporated into the project specifications. *If we are not accorded the opportunity to review these documents, we can take no responsibility for misinterpretation of our conclusions and recommendations.*

b. *Observe and advise* during all grading activities, including site preparation, foundation and retaining wall excavation, and placement of fill, to *confirm* that suitable fill soils are placed upon competent material, and to allow design changes if subsurface conditions differ from those anticipated, *prior* to the start of construction.

c. *Observe* the installation of all drainage devices.

d. *Test* all fill placed for engineering purposes to *confirm* that suitable fill materials are used and properly compacted.

7. LIMITS AND LIABILITY

All building sites are subject to elements of risk that cannot be wholly identified and/or entirely eliminated. Building sites are subject to many detrimental geotechnical hazards, including but *not* limited to the effects of water infiltration, erosion, concentrated drainage, total settlement, differential settlement, expansive soil movement, seismic shaking, fault rupture, landsliding, and slope creep. The risks from these hazards can be reduced by employing subsurface exploration, laboratory testing, analyses, and experienced geotechnical judgment. Many geotechnical hazards, however, are highly dependent on the property owner properly maintaining the site, drainage facilities, and slope and by correcting any deficiencies found during occupancy of the property in a timely manner. Even with a thorough subsurface exploration and testing program, significant variability between test locations and between sample intervals may exist. Ultimately, geotechnical recommendations are based on the experience and judgment of the geotechnical professionals in evaluating the available data from site observations, subsurface exploration, and laboratory tests. Latent defects can be concealed by earth materials, deposition, geologic history, and existing improvements. If such defects are present, they are beyond the evaluation of the geotechnical professionals. No warranty, expressed or implied, is made or intended in connection with this report, by furnishing of this report, or by any other oral or written statement. Owners and developers are responsible for retaining appropriate design professionals and qualified contractors in developing their property and for properly maintaining the property. Retaining the services of a geotechnical consultant should *not* be construed to relieve the Owner, Developer, or Contractors of their responsibilities or liabilities.

The analysis and recommendations submitted in this report are based in part on our subsurface exploration, laboratory testing, site observations, and provided data on geology and the proposed site development. Our descriptions and the boring logs may show distinctions between fill and native soils, between native (e.g., alluvium, colluvium, slopewash) and bedrock formation, and between soil type (e.g., sands and silty sands). Such distinctions were based on geologic information, grading plans when available, intermittent recovered soil/bedrock samples, and judgment. Delineations between these categories of materials may not be perfect and may be subject to change as more information becomes available. For example, judgments may be clouded when recovered samples are intermittent and small in comparison to the volume of soil under study, and macrostructure that would aid the identification process are not as apparent as they would be when the borehole is geologically downhole logged by entering the excavation. When the age of the fill is old, the difference between the structure of the fill and native materials may be less pronounced, or the degree of bedrock formation weathering sometimes makes it difficult to distinguish between overlying alluvium, colluvium, or slopewash and weathered bedrock formational material. In general, our recommendations are based more on the properties of the materials than on the category of the material type such as fill, alluvium, colluvium, slopewash, or bedrock formation. Furthermore, the actual stratigraphy may be more variable than shown on the logs.

Although this report may comment on or discuss construction techniques or procedures for the design engineer's guidance, this report should *not* be interpreted to prescribe or dictate construction procedures or to relieve the contractor in any way of their responsibility for the construction.
Please be aware that the contract fee for our services to prepare this report does not include additional work that may be required, such as grading observation and testing, footing observations, plan review, or responses to governmental (regulatory) plan reviews associated with you obtaining a building permit. Where additional services

are requested or required, you will be billed for any equipment costs and on an hourly basis for consultation or analysis.

The Geotechnical Engineer's actual scope of work during construction is very limited and does *not* assume the day-to-day physical direction of the work, minute examination of the elements, or responsibility for the safety of the contractor's workers. Our scope of services during construction consists of taking soil tests and making visual observations, sometimes on only an intermittent basis, relating to earthwork or foundation excavations for the project. We do *not* guarantee the contractor's performance, but rather look for general conformance to the intent of the plans and geotechnical report. Any discrepancy noted by us regarding earthwork or foundations will be referred to the Owner, project Engineer, Architect, or Contractor for action.

This report is issued with the understanding that it is the responsibility of the Owner, or of their representative, to ensure that the information and recommendations contained herein are called to the attention of the Architect and Engineers for the project and incorporated into the plan and that the necessary steps are taken to see that the Contractor carry out such recommendations in the field. Advanced Geotechnical Services, Inc., (AGS) has prepared this report for the exclusive use of the Client and authorized agents, and this report should *not* be considered transferable. We do recommend, however, that the report be given to future property Owners for the sole purpose of disclosing the report findings.

Findings of this report are valid as of the date of issuance. Changes in conditions of a property may occur with the passage of time whether attributable to natural processes or works of man on this or adjacent properties. Furthermore, changes in applicable or appropriate standards occur due, for example, to legislation and broadening of knowledge. Accordingly, findings of this report may be invalidated wholly or partially by changes outside our control. Therefore, *this report is subject to our review and remains valid for a maximum period of one year*, unless we issue a written opinion of its continued applicability thereafter.

In the event that any changes in the nature and design (including structural loadings different from those anticipated), or other improvements are planned, the conclusions and recommendations contained in this report shall *not* be considered valid unless the changes are reviewed and conclusions of this report modified or verified in writing.

This report may be subject to review by controlling agencies, and any modifications they deem necessary should be made a part thereof, subject to our technical acceptance of such modifications. All submissions of this report should be in its entirety. Under no circumstances should this report be summarized and synthesized to be quoted out of context for any purpose.

Test findings and statements of professional opinion do *not* constitute a guarantee or warranty, and *no* warranties, either expressed or implied, are made as to the professional advice provided under the terms of this agreement. We have strived, however, to provide our services in accordance with generally accepted geotechnical engineering practices in this community at the time of this report.

Appendix A

Field Exploration and Boring/Test Pit Logs

Appendix A
Field Exploration and Boring/Test Pit Logs

The field exploration included a site reconnaissance and subsurface exploration. During the site reconnaissance, the surface site conditions were noted, and the approximate locations of any exploration points were determined. The following descriptions of exploration methods are generic and may include methods not used on this project. Reference to the boring logs can be made to determine which methods are applicable to this project, and any differences between what is described below and actually occurred is described on the boring logs or in the main body of the report.

The test borings were advanced by either hand digging, digging with a backhoe, or drilling. In the case of drilling, a truck-mounted rotary drilling rig with a hollow-stem auger or bucket was used to advance the borings. When we expect to encounter shallow groundwater, a wet rotary drilling operation is usually used. The method actually used is noted on the boring logs. For geologic studies when the need for visual examination of the bedding and other stratigraphic features is needed along with engineering data, the larger bucket augers are used to allow a geologist to enter the excavation for visually logging the hole. When geologically logging borings and trenches, the sides are scraped prior to logging. A prefix B is used to designate a boring made with a drilling rig. When hand dug, the boring numbers have a prefix HB. When a backhoe was used, prefixes TP (test pit) or T (trench) are used. The difference between a trench and test pit being the length of the exploration; a trench being a long narrow exploration, most commonly used for fault studies. In each case, the soils were logged by technical personnel from our office and visually classified in the field in general accordance with the Unified Soil Classification system. The field descriptions have been modified as appropriate to reflect laboratory results when preparing the final boring logs.

Relatively undisturbed samples of the subsurface materials were obtained at appropriate intervals in the borings using a steel drive sampler (2.5-inches inside diameter, 3-inches outside diameter) lined with brass, one-inch-high sample rings with a diameter of 2.4 inches. This is referred to as a modified California sampler. The boring may be advanced by drilling with a hollow-stem auger or with a wet rotary operation. If below the groundwater, the hollow-stem is filled with water or drilling mud to counteract the fluid pressure of the groundwater. The sampler was usually driven into the bottom of the borehole with successive drops of a 140-pound safety hammer connected to the sampler with either A or AW rod and falling 30 inches. An automatic hammer is usually used when drilling with a CME dill rig, and a Safe-T-Driver is used when drilling with a Mobile drill rig. When above the groundwater level, a downhole Safe-T-Driver is usually used. Studies have shown that hammer efficiencies of the automatic hammer is over 90% while that of the Safe-T-Driver is about 70%, based on impact velocities. When a bucket auger is used to advance the boring, the driving weights change with depth, depending on the weight characteristics of the telescoping kelley bar, but the height of fall is usually 18 inches. Sampler driving resistance, expressed as blows per 6 inches of penetration, is presented on the boring logs at the respective sampling depths. When the borings or trenches are excavated with a backhoe, the sampler is pushed into the soil with the force of the backhoe. A hand sampler is used when the borings or trenches are advanced by hand digging or in some cases when a backhoe is used to make the excavation. This hand sampler is similar to the conventional California sampler, but lighter weight. An approximately 8-pound hammer falling about 18 inches is used to drive the hand sampler about 6 inches into the bottom of the exploration. The type of sampler used is noted on the boring logs. In some cases the hammer weight and falling distance deviate from those given above. The actual conditions are shown on the boring logs and supersede the conditions given above.

Ring samples were retained in close-fitting, moisture tight containers for transport to our laboratory for testing. Bulk samples, which were collected from cuttings, were placed in bags and transported to our laboratory for testing.

When noted on the boring logs, standard penetration test (SPT) samples were obtained using either a 20-inch or a 32-inch long split-barrel sampler with a 2-inch outside diameter and a 1.375-inch inside diameter when liners are used (1.5-inch inside diameter without liners). Unless noted otherwise, liners are used. This sampler is driven into

the soil with successive drops of a 140-pound, safety hammer falling 30 inches. The blows are recorded for each 6 inches of penetration for a total penetration of 18 or 24 inches. The sum of the number of blows for the last 12 inches of an 18-inch penetration or the middle 12 inches of a 24-inch penetration is referred to as the *N* value.

Logs, which are presented on Plates at the end of this Appendix, include a description and classification of each stratum, sample locations, blow counts, groundwater conditions encountered during drilling, results from selected types of laboratory tests, and drilling information. Keys to *Soil and Bedrock Symbols and Terms* are included on Plate A-1 and Plate A-2.

Each boring or trench, unless noted otherwise, was backfilled with cuttings at the completion of the logging and sampling. The backfill, however, may settle with time, and it is the responsibility of our client to ensure that such settlement does *not* become a liability.

Major Divisions			USCS Group Symbols	Typical Names
Coarse-Grained Soils (More than half of material is larger than No. 200 sieve)	Gravels (More than half of coarse fraction is larger than No. 4 sieve)	Clean gravels (Little or no fines)	GW	Well-graded gravels, gravel-sand mixtures, little or no fines
			GP	Poorly graded gravels, gravel-sand mixtures, little or no fines
		Gravels with fines (Appreciable amount of fines)	GM	Silty gravels, gravel-sand-silt mixtures
			GC	Clayey gravels, gravel-sand, clay mixtures
	Sands (More than half of coarse fraction is smaller than No. 4 sieve)	Clean sands (Little or no fines)	SW	Well-graded sands, gravelly sand, little or no fines
			SP	Poorly graded sands, gravelly sands little or no fines
		Sands and fines (Appreciable amount of fines)	SM	Silty sands, sand-silt mixtures
			SC	Clayey sands, sand-clay mixtures
Fine-Grained Soils (More than half of material is smaller than No. 200 sieve)	Silts and Clays Liquid Limit < 50		ML	Silts and very fine sands, rock-flour, silty or clayey fine sands, or clayey silts with slight plasticity
			CL	Inorganic clays of low or medium plasticity, gravelly clays, sandy clays, silty clays, lean clays
			OL	Organic silts and organic silty clays of low plasticity
	Silts and Clays Liquid Limit > 50		MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts
			CH	Inorganic clays of high plasticity, fat clays
	Highly Organic Soils		OH	Organic clays of medium to high plasticity, organic silts
			Pt	Peat and other highly organic soils

Legend of Laboratory Tests

G - Grain Size	C - Consolidation	PP - Pocket Penetrometer
A - Atterberg Limits	DS - Direct Shear	CH - Chemical
P - Compaction	U - Unconfined	
S - Swell/Expansion	T - Triaxial	

Sampler Type

Modified California / Hand Sampler — SPT / Shelby Tube — Rock Core / Bulk — No Recovery

Terms used in this report for describing soils according to their texture or grain size distributions are generally in accordance with the Unified Soil Classification System.

Terms Describing Density and Consistency

Coarse Grained soils (major portion retained on No. 200 sieve) include (1) clean gravels, (2) silty or clayey gravels, and (3) silty, clayey, or gravelly sands. Relative density is related to SPT blow count corrected for overburden pressure or drive energy.

Density		SPT *N* Value Blows/Ft	Relative Density %
Very Loose	vl	0 to 4	0 to 15
Loose	l	4 to 10	15 to 35
Medium Dense	md	10 to 30	35 to 65
Dense	d	30 to 50	65 to 85
Very Dense	vd	> 50	85 to 100

Fine Grained soils (major portions passing No. 200 sieve) include (1) inorganic and organic silts and clays, (2) gravelly, sandy, or silty clays, and (3) clayey silts. Consistency is rated according to shear strength as indicated by penetrometer readings, direct shear, or SPT blow count.

Consistency	Shear Strength, ksf	SPT *N* Value
Very Soft	< 0.25	0 to 2
Soft	0.25 to 0.50	2 to 4
Firm	0.50 to 1.00	4 to 8
Stiff	1.00 to 2.00	8 to 16
Very Stiff	2.00 to 4.00	16 to 32
Hard	> 4.00	> 32

Terms Characterizing Soil Structure

Slickensided	Having inclined planes of weakness that are slick and glossy in appearance.
Fissured	Containing shrinkage cracks, frequently filled with fine sand or silt; usually more or less vertical.
Laminated	Composed of thin layers of varying color and texture.
Interbedded	Composed of alternate layers of different soil types.
Calcareous	Containing appreciable quantities of calcium carbonate.
Well Graded	Having wide range in grain sizes and substantial amounts of intermediate particle sizes.
Poorly Graded	Predominately one grain size, or having a range of grain sizes with some intermediate sizes missing.
Porous	Having visibly apparent void spaces through which water, air, or light may pass.

Soil Moisture

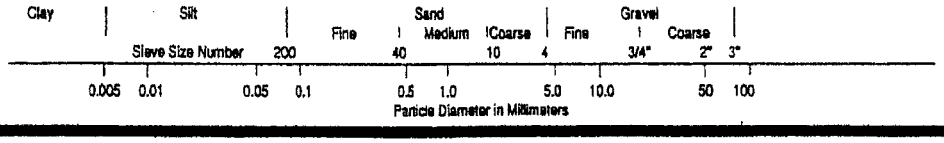
From low to high, the moisture content is indicated by:

Dry	D
Slightly Moist	Sl M
Moist (near optimum for compaction)	M
Very Moist	V M
Wet	W

Size Proportions

Designation	Percent by Weight
Trace	< 5
Few	5 to 10
Little	15 to 25
Some	30 to 45

Grain Size Distribution



Advanced Geotechnical Services

Key to Bedrock Symbols and Terms

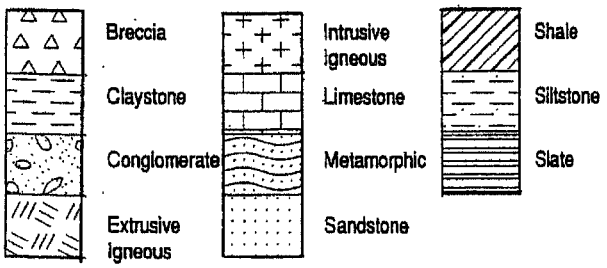
Degree of Weathering
Diagnostic Feature

Descriptive Term	Discoloration Extent	Fracture Condition	Surface Characteristics	Original Texture	Grain Boundary Condition
Unweathered	None	Closed or discolored	Unchanged	Preserved	Tight
Slightly Weathered	Less 20% of fracture spacing on both sides of fracture	Discolored, may contain thin filling	Partial discoloration	Preserved	Tight
Moderately Weathered	Greater than 20% of fracture spacing on both sides of fracture	Discolored, may contain thick filling, cemented rock	Partial to complete discoloration, not friable except poorly cemented rocks	Preserved	Partial Opening
Highly Weathered	Throughout		Friable and possibly pitted	Mainly Preserved	Partial Separation
Completely Weathered	Throughout		Resembles a soil	Partly Preserved	Complete Separation

Discontinuity Spacing

Description for Structural Feature: Bedding, Foliation, or Flow Banding	Spacing		Description for Joints, Faults, or Other Fractures
Very Thickly (Bedded, Foliated, or Banded)	More than 2 m	More than 6 ft	Very Widely (Fractured or Jointed)
Thickly	60 cm to 2 m	2 to 6 ft	Widely
Moderately	20 to 60 cm	8 to 24 in.	Medium
Thinly	60 to 200 mm	2.5 to 8 in.	Closely
Very Thinly	20 to 60 mm	0.75 to 2.5 in.	Very Closely
Description for Microstructural Features: Bedding, Foliation, or Cleavage			
Intensely (Laminated, Foliated, or Cleaved)	6 to 20 mm	0.25 to 0.75 in.	Extremely Close
Very Intensely	< 6 mm	< 0.25 in.	

Graphic Symbols - Bedrock



Rock Hardness

Classification	Field Test
Very Weak	Can be dug by hand and crushed with fingers.
Weak	Friable, can be gouged deeply with a knife and will crumble readily under light hammer blows.
Moderately Strong	Can be peeled with a knife. Material crumbles under firm blows with the sharp end of a geologic pick.
Strong	Cannot be scaped or peeled with a knife point. Hand held specimen breaks with firm blows of the pick.
Very Strong	Difficult to scratch with knife point. Cannot break hand held specimen.

Separation of Fracture Walls

Description	Separation of Walls, mm
Closed	0
Very Narrow	0 to 0.1
Narrow	0.1 to 1.0
Wide	1.0 to 5.0
Very Wide	> 5.0

Fracture Filling

Description	Definition
Clean	No fracture filling material
Stained	Discoloration of rock only. No recognizable filling material.
Filled	Fracture filled with recognizable filling material.

Surface Roughness

Description	Classification
Smooth	Appears smooth and is essentially smooth to the touch. May be slickensided.
Slightly Rough	Asperities on the fracture surfaces are visible and can be distinctly felt.
Medium Rough	Asperites are clearly visible and fracture surface feels abrasive to the touch.
Rough	Large angular asperites can be seen. Some ridge and high-side angle steps evident.
Very Rough	Near vertical steps and ridges occur on the fracture surface.

Where slickensides are observed, the direction of the slickensides should be recorded after the standard discontinuity surface description.

Appendix B

Laboratory Testing

Appendix B
Laboratory Testing

A laboratory test program is designed for each project to evaluate the physical and mechanical properties of the soil and bedrock materials encountered at the site during our field exploration program. Laboratory tests were conducted on representative samples for the purpose of classification and determining their properties for use in analyses and evaluations. The most common laboratory tests include moisture-density, Atterberg limits, grain-size analyses (sieve and hydrometer analyses), sand equivalent, direct shear, consolidation, compaction, expansion index, and *R*-values. The following descriptions of test methods are generic and may include methods not used on this project. Reference to the boring logs and test results on Plates attached to this appendix will show which tests were performed for this project. Laboratory testing is performed in general accordance with the most recent ASTM test designations available at the time of testing.

Classification Tests

Classification testing is performed to identify differences in material behavior and to correlate the results with shear strength and volume change characteristics of the materials. Classification testing includes unit weight (e.g., dry density), moisture content, Atterberg limits, grain size analyses (sieve and hydrometer), and sand equivalent.

Moisture-Density Test

Site soils were classified in the laboratory in accordance with the Unified Soil Classification System. Moisture contents are performed in general accordance with ASTM Test Designation D2216 and unit weights were determined in general accordance with ASTM Test Designation D2937. Field moisture contents and dry unit weights were determined for the ring samples obtained in the field. Field moisture contents and dry unit weights are shown on the boring logs in Appendix A.

Sieve Analysis

Sieve analysis tests were conducted on the on-site soils in general accordance with sieve analysis test procedure from ASTM Test Designation D422. This method covers the quantitative determination of the distribution of particle sizes in soils. If this test was performed, the results are presented on Plates attached to this appendix.

Hydrometer Test

Hydrometer tests were performed in general accordance with ASTM Test Designation D422. If this test was performed, the results are presented on Plates attached to this appendix. Samples with obviously little course material and a high percentage of fines were prepared with a wet method (ASTM Test Designation D2217) rather than air-drying the sample and pulverizing with a mortar and pedestal.

Shear Tests

Direct shear tests were performed in general accordance with ASTM D3080 to determine the shear strength parameters of undisturbed on-site soils or remolded soil specimens. The samples are usually tested in an artificially saturated condition. This is accomplished by soaking the specimens in a confined container for a period of one or 2 days, depending on the permeability of the material. The specimen, 1-inch-high and 2.4-inch-diameter, is placed in the shear device, and a vertical stress is applied to the specimen. The specimen is allowed to reach an equilibrium state (swell or consolidate). The specimen is then sheared under a constant rate of deformation. The rate of deformation for a slow test, sufficiently slow to presumably allow drainage, is selected from computed or measured consolidation rates to simulate full drainage (full dissipation of any tendency for pore water pressure changes) during shear. A rate of displacement of 0.005 inches per minute was used for the most tests. The process usually is repeated for 3 specimens, each under different vertical stresses. The results from the 3 tests are plotted on a diagram of shear stress and normal (vertical) stress at failure, and linear approximations are drawn of the failure curves to determine the angle of internal friction and cohesion. The first moisture content shown on the graphs

(associated with peak values) is for either the in-situ condition or the remolded condition, and the second moisture content (associated with ultimate value) is for the soaked condition.

Consolidation Test

Consolidation tests were performed in general accordance with ASTM D2435 and D5333 on selected samples to evaluate the load-deformation characteristics of the earth soils. The tests were performed primarily on material that would be most susceptible to consolidation under anticipated foundation loading. The soil specimen, contained in a 2.4-inch-diameter, 1.0-inch-high sampling ring, is placed in a loading frame under a seating pressure of 0.1 ksf. Vertical loads are applied to the samples in several geometric increments, and the resulting deformations were recorded at selected time intervals. When the pressure reaches a preselected effective overburden pressure (often 2 ksf) and the specimen has consolidated under that pressure, the laboratory technician adds water to the test cell and records the vertical movement. After the specimen reaches equilibrium with the addition of water, the technician continues the loading process, usually up to a pressure of about 8 ksf. The specimen is then unloaded in increments, and the test is dismantled. The results of the test are presented in terms of percent volume change versus applied vertical stress. If this test was performed, the results are presented on Plates attached to this appendix.

Compaction Test

Compaction tests provide information on the relationship between moisture content and dry density of the soil compacted in a given manner. The maximum density is obtained for a given compaction effort at an optimum moisture content. Specifications for earthwork are in terms of the unit weight (or dry density) expressed as a percentage of the maximum density, and the moisture content compared to the optimum moisture content. Compaction tests were performed in general accordance with ASTM Test Designation D1557 to determine the maximum dry densities and optimum moisture contents of the on-site soils. If this test was performed, the results are presented on Plates attached to this appendix.

Expansion Index Test

The expansion index test provides an assessment of the potential for expansion or heave that could be detrimental to foundation or slab performance. Expansion Index tests are performed on shallow on-site soils in general accordance with expansion test procedures in ASTM D4829. In this test, a specimen is compacted at a degree of saturation between 45% and 55% in a 4.01-inch-diameter, 1.0-inch-high ring. The specimen is subjected to a seating pressure of 144 psf, water is added to the test cell, and swell is monitored until the expansion stops. The volume of swell is converted to an expansion index. Any test results are summarized on the boring logs in Appendix A.

Sample Remolding

In some cases, remolded samples are used when performing direct shear tests and consolidation tests. Samples are remolded to a specified moisture and density by compacting the soil in a 2.42-inch-diameter sample ring. The specified moisture content is either at optimum or a few percentage points above optimum. The specified dry density is usually at a relative compaction of 90%. The required moisture is added to and mixed with dry soil, providing a homogeneous mixture. A 2.42-inch-diameter ring is placed in a 6-inch-diameter compaction mold, and soil is placed in the mold to above the ring. The soil is then compacted with a 5.5-pound hammer with a free-fall drop of 12 inches. The sample is trimmed, and the dry density is determined. If the dry density deviates more than about one pound per cubic foot from the specified dry density, the process is repeated with the number of blows altered to better achieve the specified dry density.

Prepared for: Advanced Geotechnical Services
5251 Verdugo Way, Suite L
Camarillo, CA 93012
Attn: Jim Bruss

Report Date: December 1, 2022
Laboratory Number: 221786
Purchase Order No: 5251-1360
Project Name: Ventura Ranch Partners, LLC 5251 Lab 1360
Sampled by: Lonny Padilla

Enclosed are the analysis results for samples received November 14, 2022 with the Chain of Custody document. The samples were received in good condition, at 21.3°C, and they were identified and assigned the laboratory ID numbers listed below:

SAMPLE DESCRIPTION	CAS LAB NUMBER ID
B-1@0-5'	221786-01
B-2@0-5'	221786-02

By my signature below, I certify that the results contained in this laboratory report comply with applicable standards for certification by the California Department of Public Health's Environmental Laboratories Accreditation Program (ELAP), both technically and for completeness, and that, based on my inquiry of the person or persons directly responsible for performing the analyses, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete.

SUBJECT: R-Value Testing
Samples Delivered to Laboratory

Gentlemen:

Pursuant to your request, R-Value testing was performed on a soil sample delivered to our laboratory. R-Value testing was performed in accordance with California Test 301-F criteria. The test results follow:

R-VALUE RESULTS

PROJECT: Ventura Ranch Partners, #5152, Lab # 1360
LOCATION: B-1 @ 0 – 5'
Soil Description: Dark Brown Fine Sandy Clay

ITEM	1	2	3
Compaction Pressure – psi	150/175	125/150	150/200
Initial Moisture - %	13.6	13.6	13.6
Moisture at Compaction - %	15.5	16.0	15.0
Density – pcf	113.3	112.7	112.8
R-Value	11	9	14
Exudation Pressure	324	271	395
Expansion Pressure thickness ft.	0.00	0.00	0.10

Assigned R-Value: 10*

Footnote:
**Please verify R-value based upon expansion thickness (see California Test 301-F procedures).*

Thank you for allowing *Pacific Materials Laboratory, Inc.* to be of service. If we may be of further service regarding this or other geotechnical issues, please do not hesitate to call (805) 482-9801, write or email at pmlgeo@gmail.com.

Respectfully Submitted,

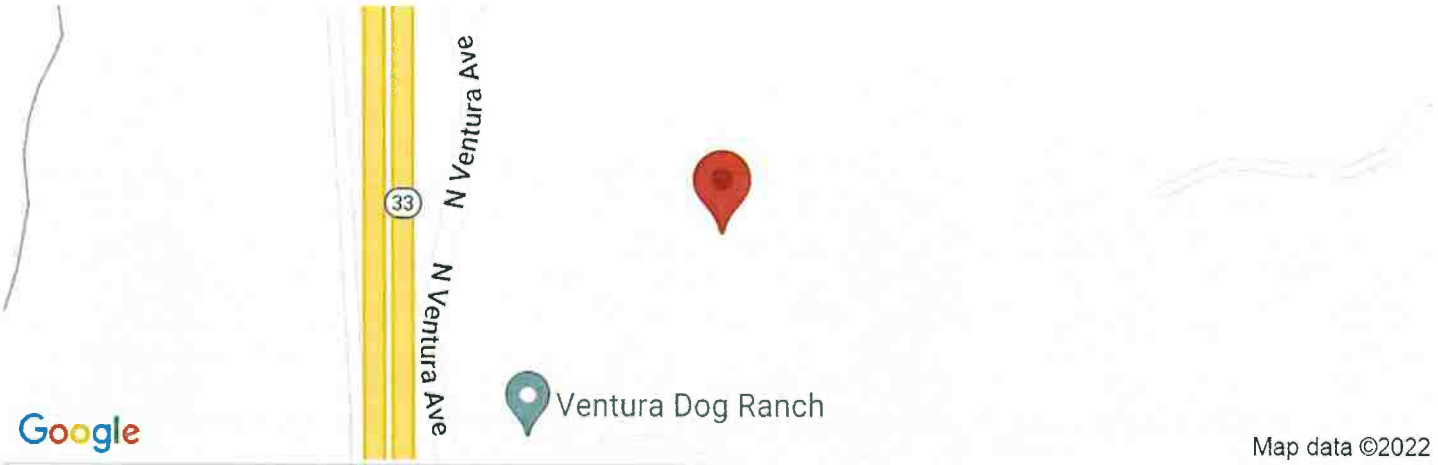
Seismic Design Criteria

Ventura Ranch Partners

Latitude, Longitude: 34.332963, -119.289392



Date	11/30/2022, 11:51:04 AM
Design Code Reference Document	ASCE7-16
Risk Category	II
Site Class	D - Stiff Soil

Type	Value	Description
S_S	2.108	MCE_R ground motion. (for 0.2 second period)
S_1	0.794	MCE_R ground motion. (for 1.0s period)
S_{MS}	2.108	Site-modified spectral acceleration value
S_{M1}	null -See Section 11.4.8	Site-modified spectral acceleration value
S_{DS}	1.406	Numeric seismic design value at 0.2 second SA
S_{D1}	null -See Section 11.4.8	Numeric seismic design value at 1.0 second SA

Type	Value	Description
SDC	null -See Section 11.4.8	Seismic design category
F_a	1	Site amplification factor at 0.2 second
F_v	null -See Section 11.4.8	Site amplification factor at 1.0 second
PGA	0.929	MCE_G peak ground acceleration
F_{PGA}	1.1	Site amplification factor at PGA
PGA_M	1.022	Site modified peak ground acceleration
T_L	8	Long-period transition period in seconds
SsRT	2.108	Probabilistic risk-targeted ground motion. (0.2 second)
SsUH	2.4	Factored uniform-hazard (2% probability of exceedance in 50 years) spectral acceleration
SsD	2.466	Factored deterministic acceleration value. (0.2 second)
S1RT	0.794	Probabilistic risk-targeted ground motion. (1.0 second)
S1UH	0.906	Factored uniform-hazard (2% probability of exceedance in 50 years) spectral acceleration.
S1D	0.854	Factored deterministic acceleration value. (1.0 second)
PGAd	1.004	Factored deterministic acceleration value. (Peak Ground Acceleration)
PGA_{UH}	0.929	Uniform-hazard (2% probability of exceedance in 50 years) Peak Ground Acceleration
C_{RS}	0.878	Mapped value of the risk coefficient at short periods
C_{R1}	0.877	Mapped value of the risk coefficient at a period of 1 s
C_V	1.5	Vertical coefficient

Subject: Phase I Environmental Site Assessment, Ventura Ranch Farmworker Housing Complex 4884 North Ventura Avenue, Ventura, California

Dear Mr. Conger:

This report presents the findings of a Phase I Environmental Site Assessment (ESA) completed by Rincon Consultants, Inc. (Rincon) for the Ventura Ranch Farmworker Housing Complex property located at 4884 North Ventura Avenue in Ventura, California. The Phase I ESA was performed in accordance with our proposal dated November 6, 2024 and contract dated January 10, 2025.

The accompanying report presents our findings and provides an opinion regarding the presence of recognized environmental conditions in connection with the subject property. Our work program for this project, as referenced in our contract, is intended to meet the guidelines outlined in the ASTM International (ASTM) Standard Practice for Environmental Site Assessments: *Phase I Environmental Site Assessment Process* (ASTM Standard E1527-21). Our scope of services, pursuant to ASTM practice, did not include any inquiries with respect to asbestos-containing building materials unrelated to releases into the environment; biological agents; cultural and historic resources; ecological resources; endangered species; health and safety; indoor air quality unrelated to releases of hazardous substances or petroleum products into the environment; industrial hygiene; lead-based paint unrelated to releases into the environment; lead in drinking water; mold or microbial growth conditions; polychlorinated biphenyl-containing building materials (e.g., interior fluorescent light ballasts, paint, and caulk); naturally-occurring radon; regulatory compliance; substances not defined as hazardous substances (including some substances sometimes generally referred to as emerging contaminants) unless or until such substances are classified as a Comprehensive Environmental Response, Compensation, and Liability Act hazardous substance; and wetlands.

Thank you for selecting Rincon for this project. If you have any questions, or if we can be of any future assistance, please contact us.

Sincerely,
Rincon Consultants, Inc.

Executive Summary

This report presents the findings of a Phase I Environmental Site Assessment (ESA) for the property located at 4884 North Ventura Avenue in Ventura, California (subject property). The Phase I ESA was performed for the County of Ventura Resources Management Agency Planning Division by Rincon Consultants, Inc. (Rincon). The County of Ventura Resources Management Agency Planning Division has requested this assessment and will use the information for the purpose of determining potential environmental concerns on the subject property. The subject property currently includes a single-family residence and barn, agricultural land, and undeveloped land. It is our understanding that the proposed future use of the subject property includes the development of a farmworker housing complex.

The research completed as part of this Phase I ESA is listed below:

Task	Completed	Date Reviewed	Finding Identified
User-Provided – Title Report	Requested	Not Applicable (N/A)	N/A
User-Provided – Lien Search Report	Requested	N/A	N/A
Interviews – User Questionnaire	Yes	02/09/2025	Yes
User-Provided – Additional Documents	Requested	N/A	N/A
Physical Setting Resources – Topography	Yes	02/05/2025	No
Agency Database Report	Yes	02/05/2025	Yes
Agency File Reviews	Yes	02/05/2025	Yes
Vapor Migration Research	Yes	02/05/2025	No
Historical Research – Aerial Photographs	Yes	02/25/2025	Yes
Historical – Topographic Maps	Yes	02/25/2025	Yes
Historical – Fire Insurance Maps	Yes, none available	N/A	N/A
Historical – City Directories	Yes	02/25/2025	No
Interviews – Owner Questionnaire	Yes	02/07/2025	Yes
Interviews – Other	No	N/A	N/A
Site Reconnaissance	Yes	02/05/2025	Yes

Based on the findings of this Phase I ESA, it is our opinion that there are environmental concerns in connection with the subject property as follows.

Finding	Opinion	Conclusion	Recommendation
Current and former agricultural use of the subject property	According to the historical resources reviewed, the subject property appears to have been used for agricultural purposes as an orchard from approximately 1926 to present. During the site reconnaissance, active orchards were observed on the subject property. Agricultural land use is typically associated with the use of pesticides.	REC	Subsurface investigation in areas planned for ground disturbance
Stored vehicles, equipment, and solid waste, including aboveground storage tanks (ASTs) with unknown contents on the subject property	During the site reconnaissance, various stored vehicles, equipment, machinery, and solid waste were observed in the southwestern corner of the subject property near the barn. Minor soil and concrete staining was observed in these areas. Additionally, two abandoned ASTs were observed within the orchard area on the subject property. Indications of releases were not observed in the vicinity of these features.	Notable Finding	Proper removal and offsite disposal prior to redevelopment Soil Management Plan
Potential asbestos-containing materials (ACM) and lead-based paint (LBP) at the subject property	Based on the age of the onsite structures (constructed as early as 1959), ACM and LBP may be present in building materials at the subject property.	Notable Finding	ACM and LBP survey prior to demolition or renovation of onsite structures
Potential presence of aerially deposited lead (ADL) in shallow soil on the subject property	According to the historical resources reviewed, Highway 33 was constructed adjacent to the west of the subject property by 1941 (originally identified as Route 399). Elevated concentrations of lead may exist in soils along older roadways as a result of ADL from the historical use of leaded gasoline in motor vehicles. Based on the presence of Highway 33 adjacent to the west of the subject property (approximately 220 feet away) during the time period that leaded gasoline was used in motor vehicles (1920s to 1992; California Department of Toxic Substances Control [DTSC] 2016), there is a potential for elevated concentrations of ADL to be present in onsite shallow soil. However, elevated concentrations of lead are typically found in the top 6 inches and within 20 feet of the roadways, with maximum concentrations within approximately 10 feet (DTSC 2016).	Notable Finding	None
Reported per- and polyfluoroalkyl substances (PFAS) in effluent within one mile of the subject property	According to the California Statewide Drinking Water System Quarterly Testing Results online Public Map Viewer (Table 4), perfluorooctanoic acid (PFOA) was detected in Ojai Valley Wastewater Treatment Plant effluent samples collected approximately 0.9 mile from the subject property at concentrations greater than their respective State Water Resources Control Board notification and response levels. However, PFOA and perfluorooctane sulfonic acid (PFOS) were not detected above laboratory reporting limits in Ventura River Water District drinking water wells approximately 7 miles from the subject property. It is unknown if concentrations of PFAS have an impact on water quality with Ventura Water's service area. For information regarding potable water quality provided to the subject property, contact Ventura Water.	Notable Finding	Contact Ventura Water

Finding	Opinion	Conclusion	Recommendation
Nearby release site with no information available	According to the database report, a nearby property at the 5000 block of North Ventura Avenue was listed on a release database. No additional information pertaining to the location or type of release was provided by Environmental Risk Information Services or available on GeoTracker, EnviroStor, or the Ventura County Environmental Health Division online records portal.	Notable Finding	Soil Management Plan
Previous small-quantity releases reported at the subject property	The HAZR Ventura regulatory database indicates that a release of 5-10 gallons of smudge oil due to a standpipe leak occurred onsite in 1990 and a release of two gallons of polychlorinated biphenyl oil from a pole-top transformer occurred onsite in 2011 and was removed by a contractor. However, the locations of these releases are unknown.	De minimis	Soil Management Plan
Deviation from ASTM Standard	The interiors of the onsite residence and residential garage were not observed during the site reconnaissance.	Deviation resulting in possible data gap	Observe interiors of onsite buildings if evidence of hazardous materials use

1 Introduction

This report presents the findings of a Phase I Environmental Site Assessment (ESA) conducted for the property located at 4884 North Ventura Avenue in Ventura, California (subject property; Figure 1). The Phase I ESA was performed by Rincon Consultants, Inc. (Rincon) for the County of Ventura Resources Management Agency Planning Division in general conformance with ASTM International (ASTM) Standard E1527-21, our proposal dated November 6, 2024, and our contract dated January 10, 2025. This report presents our findings and provides our opinion as to the presence of recognized environmental conditions (RECs) on the subject property.

1.1 Subject Property Description

The subject property is located at 4884 North Ventura Avenue and Assessor's Parcel Number (APN) 063-0-110-065, -035, -090, -145 and is located east of North Ventura Avenue in Ventura, Ventura County, California (Figure 2). Additional information regarding subject property conditions observed during site reconnaissance is provided in Section 6.

1.2 General Vicinity Characteristics

The subject property is located in an area that is primarily composed of residential and agricultural land uses.

1.3 Purpose and Definitions

The County of Ventura Resources Management Agency Planning Division has requested this assessment and will use the information for the purpose of determining potential environmental concerns on the subject property. The purpose of this Phase I ESA was to determine if there are RECs on the subject property, taking into account commonly and reasonably ascertainable information, and to qualify for Landowner Liability Protections under the Brownfields Amendments to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

A **REC** is defined pursuant to ASTM E1527-21 as, "(1) the presence of hazardous substances or petroleum products in, on, or at the subject property due to a release to the environment; (2) the likely presence of hazardous substances or petroleum products in, on, or at the subject property due to a release or likely release to the environment; or (3) the presence of hazardous substances or petroleum products in, on, or at the subject property under conditions that pose a material threat of a future release to the environment." As stated in ASTM E1527-21, "**likely** is that which is neither certain nor proved, but can be expected or believed by a reasonable observer based on the logic and/or experience of the environmental professional, and/or available evidence, as stated in the report to support the opinions given therein."
A **Controlled REC** is defined pursuant to ASTM E1527-21 as, "recognized environmental condition affecting the subject property that has been addressed to the satisfaction of the applicable regulatory authority or authorities with hazardous substances or petroleum products allowed to remain in place subject to implementation of required controls (for example, activity and use limitations or other property use limitations)."
A **Historical REC** is defined pursuant to ASTM E1527-21 as, "a previous release of hazardous substances or petroleum products affecting the subject property that has been addressed to the satisfaction of the applicable regulatory authority or authorities and meeting unrestricted use criteria established by the applicable regulatory authority or authorities without subjecting the subject property to any controls (for example, activity and use limitations or other property use limitations). A historical recognized environmental condition is not a recognized environmental condition."
A ***de minimis*** condition is defined pursuant to ASTM E1527-21 as, "a condition related to a release that generally does not present a threat to human health or the environment and that generally would not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies. A condition determined to be a de minimis condition is not a recognized environmental condition nor a controlled recognized environmental condition."
A **Property Use Limitation** is defined pursuant to ASTM E1527-21 as, "a limitation or restriction on current or future use of a property in connection with a response to a release, in accordance with the applicable regulatory authority or authorities that allows hazardous substances or petroleum products to remain in place at concentrations exceeding unrestricted use criteria."
A **Significant Data Gap** is defined pursuant to ASTM E1527-21 as, "a data gap that affects the ability of the environmental professional to identify a recognized environmental condition."

1.3.1 Notable Finding

Although not defined by ASTM E1527-21, Rincon utilizes the term *Notable Finding* for potential environmental concerns present at or possibly present at a property that do not specifically fit one of the above ASTM-defined situations, yet may impact current or future use of the subject property.

1.4 Scope of Services

The scope of services conducted during this study is outlined below:

- Performed a reconnaissance of the subject property to identify obvious indicators of the existence of hazardous materials.
- Observed adjacent or nearby properties from public thoroughfares in an attempt to see if such properties are likely to use, store, generate, or dispose of hazardous materials.
- Obtained and reviewed an environmental records database search to obtain information about the potential for hazardous materials to exist at the subject property or at properties located in the vicinity of the subject property.
- Reviewed files for the subject property and immediately adjacent properties as identified in the database report, as applicable.
- Reviewed the current United States Geological Survey (USGS) topographic map to obtain information about the subject property and regional topography and uses of the subject property and surrounding sites.
- Reviewed additional pertinent record sources (e.g., California Geologic Energy Management Division [CalGEM] records, online databases of hazardous substance release sites), as necessary, to identify the presence of RECs at the subject property.
- Reviewed the California State Water Resources Control Board (SWRCB) Statewide Per- and Polyfluoroalkyl Substances (PFAS) Investigation online Public Map Viewer regarding current PFAS orders issued to facilities located in the vicinity of the subject property.
- Reviewed reasonably ascertainable historical resources (e.g., aerial photographs, topographic maps, fire insurance maps, city directories) to assess the historical land use of the subject property and adjacent properties.
- Provided a user interview questionnaire to a representative of County of Ventura Resources Management Agency Planning Division, the user of the Phase I ESA.
- Provided a property owner interview questionnaire to the property owner or a designated subject property representative identified to Rincon by County of Ventura Resources Management Agency Planning Division.
- Conducted interviews with other property representatives (e.g., key site manager, occupants), as applicable.
- Reviewed available County of Ventura Resources Management Agency Planning Division-provided information (e.g., previous environmental reports, title documentation).
- Requested Title Search Information Reports and environmental lien search information from the user of the report.

1.5 User Reliance

The County of Ventura Resources Management Agency Planning Division has requested this assessment and will use the information for the purpose of determining potential environmental concerns on the subject property. This Phase I ESA was prepared for use solely and exclusively by the County of Ventura Resources Management Agency Planning Division. No other use or disclosure is intended or authorized by Rincon. Also, this report is issued with the understanding that it is to be used only in its entirety. It is intended for use only by the County of Ventura Resources Management Agency Planning Division, and no other person or entity may rely upon the report without the express written consent of Rincon.

2 User-Provided Information and Responsibilities

2.1 Review Land Title Records and Judicial Records for Environmental Liens and Activity and Use Limitations

Rincon requested title search information reports from the user of the report. Pursuant to ASTM E1527-21,

> "the title search information reports shall identify environmental covenants, environmental easements, land use covenant and agreements, declaration of environmental land use restrictions, environmental land use controls, environmental use controls, environmental liens, or any other recorded instrument that restricts, affects, or encumbers the title to the subject property due to restrictions or encumbrances associated with the presence of hazardous substances or petroleum products. Title search information reports shall review land title records for documents recorded between 1980 and the present. If judicial records are not reviewed, the title search information report shall include a statement providing that the law or custom in the jurisdiction at issue does not require a search for judicial records in order to identify environmental liens."
>
> As stated in ASTM E1527-21 it is the "user's responsibility to search for environmental liens and activity and land use limitations (AULs)." This is in "addition to the environmental professional's search of institutional control and engineering control registries described in" ASTM E1527-21 Section 8.2.

As of the date of this report, title search information records have not been provided to Rincon.

2.2 User Questionnaire

As described in ASTM E1527-21 Section 6, a User Questionnaire as provided by ASTM E1527-21 Appendix X3 was provided to the County of Ventura Resources Management Agency Planning Division. The purpose of the User Questionnaire is for the user of the Phase I ESA to provide actual knowledge pertaining to the subject property to help identify RECs. Jena Albert, Trustee, Meyerstein Trust, completed the User Questionnaire on February 9, 2025. A copy of the completed questionnaire is included as Appendix A.

Based on our review of the completed questionnaire, the user indicated the information in Table 1.

Table 1 User-Provided Information

Question	Yes	No	Unknown	Comment
Why is the Phase I ESA required or being performed?	–	–	–	To purchase the subject property for farmworker housing
What type of transaction is planned for the subject property?	–	–	–	Purchase/Sale
Did the user's search of recorded land title records (or judicial records, where appropriate), identify any environmental liens filed or recorded against the subject property?	☐	☐	☒	Unknown
Did the user's search of recorded land title records (or judicial records, where appropriate), identify any AULs that are in place at the subject property and/or have been filed or recorded against the subject property under federal, tribal, state, or local law?	☐	☐	☒	Unknown
Is the user aware of specialized environmental knowledge or experience related to the subject property or nearby properties?	☐	☐	☒	Unknown
Is the user aware of any reduction in value of the subject property relative to any known environmental issues?	☐	☒	☐	The user believes the purchase price being paid for the subject property reasonably reflects the fair market value of the property.
Is the user aware of commonly known or reasonably ascertainable information about the subject property that would help Rincon to identify conditions indicative of releases or threatened releases?	☒	☐	☐	Historical agricultural and residential use on subject property
Is the user aware of any obvious indicators that point to the presence or likely presence of releases at the subject property?	☐	☒	☐	None
Is the user aware of any pending, threatened, or past litigation relevant to hazardous substances or petroleum products in, on, or from the subject property?	☐	☒	☐	None
Is the user aware of any pending, threatened, or past administrative proceedings relevant to hazardous substances or petroleum products in, on, or from the subject property?	☐	☒	☐	None
Is the user aware of any notice from any government entity regarding any possible violation of environmental laws or possible liability relating to hazardous substances or petroleum products at the subject property?	☐	☒	☐	None

Based on our review of the completed questionnaire, the user provided additional information pertaining to the subject property that may help identify RECs in connection with the subject property. The user noted that there is potential pesticide/herbicide presence due to historical agricultural operations on the property.

3 Physical Setting and Government Records

3.1 Physical Setting – Topography

The current USGS topographic map (Ventura Quadrangle 2022) indicates that the subject property is situated at elevations ranging from approximately 200 to 740 feet above mean sea level with topography sloping down to the southwest. The adjacent topography also consists of west/southwest-sloping topography towards the Ventura River. A copy of the current USGS topographic map is included in Appendix B (ERIS 2025e).

3.2 Government Record Sources and Agency Records Review

Rincon outsourced with a regulatory database search contractor, Environmental Risk Information Services (ERIS), to obtain records of sites that generate, store, treat, or dispose of hazardous materials and sites for which a hazardous material release incident has occurred. The regulatory database search was conducted for the subject property and included data from surrounding sites within specified radii of the subject property. A copy of the database report, which specifies the ASTM E1527-21 search distance for each public list, is included as Appendix C. As shown on the ERIS database report, federal, state, and county lists were reviewed as part of the research effort. Please refer to Appendix C for a complete listing of sites reported by ERIS and a description of the databases reviewed.

The Map Findings Summary, included in the database report, provides a summary of the databases searched, the number of reported facilities within the search radii, and whether the facility is located onsite or adjacent to the subject property.

As a follow-up to the database search, Rincon reviewed regulatory information for the subject property and nearby listings that were interpreted to have the potential to impact the subject property, based on one or more of the factors listed below:

- Reported distance of the facility from the subject property;
- The nature of the database on which the facility is listed, and/or whether the facility was listed on a database reporting unauthorized releases of hazardous materials, petroleum products, or hazardous wastes;
- Reported case type (e.g., soil only, failed underground storage tank [UST] test only);
- Reported substance released (e.g., chlorinated solvents, gasoline, metals);
- Reported regulatory agency status (e.g., case closed, “no further action”); and,
- Location of the facility with respect to the reported groundwater flow direction (discussed in Section 3.2.2 of this report).

Facilities/properties that were interpreted by Rincon to be of potential environmental concern to the subject property, based on one or more of the factors listed above, are summarized below. In accordance with ASTM E1527-21, contamination migration pathways in soil, groundwater, and soil vapor were considered in our analysis of offsite properties of potential environmental concern.

The following sections include a summary of our review of the database report and the regulatory information obtained from online sources (e.g., SWRCB GeoTracker database, Department of Toxic Substances Control [DTSC] EnviroStor database, local fire department) and/or files requested from the applicable regulatory agency.

3.2.1 Subject Property, Adjacent Properties, Orphan Listings, and National Priorities List Sites Summary

The ERIS database report identified listings for the subject property, adjacent properties, orphan sites, and/or National Priorities List (NPL) sites as summarized below in Table 2.

Table 2 Subject Property, Adjacent Properties, Orphan Listings, and NPL Sites Summary

Site	Listings	Database Reference/Address	Finding Identified	Comment
Subject Property	Yes	ERNS, **CHMIRS**, **HAZR Ventura** (4884 N Ventura Ave.)	Yes	Release of 2 gallons of polychlorinated biphenyl (PCB) oil from pole-top transformer with "only few drops" to the storm drain in 2011. Handled/stored hazardous materials and/or generated hazardous waste; no releases reported.
		Haz Gen, **HAZR Ventura** (Bernard Ranch at 4884 N Ventura Ave.)	Yes	Release of 5-10 gallons of smudge oil due to standpipe leak in 1990, location unknown.
Adjacent Properties	Yes	Northern Adjacent – RCRA Non Gen (Pozzebon Backhoe Service Inc. at 420 Canada Larga Rd.)	No	Generated hazardous waste; no releases reported
		Northwestern Adjacent – Haz Gen (Catherine Douglas at 306 E. Bounds Rd.)	No	Handled/stored hazardous materials and/or generated hazardous waste; no releases reported
		Northwestern Adjacent – HAZR (Ventura at Ventura Ave. & Norway Ave.)	No	Release of 1 gallon of gasoline reported in 1988, location unknown. Not likely to pose a risk due to small quantity.
		Northwestern Adjacent – Haz Gen (Ellen Marshal at 5232 Floral Dr.)	No	Handled/stored hazardous materials and/or generated hazardous waste; no releases reported
		Southern Adjacent – Haznet (Howard Supply Company LLC at 4800 N. Ventura Ave.)	No	Handled/stored hazardous materials and/or generated hazardous waste; no releases reported
		Southern Adjacent – **CalSites**, Envirostor, SCH (Westside Elementary School at 4584 North Ventura Ave.)	Yes	Previous residence and agriculture land, entered into Voluntary Cleanup Agreement with DTSC for proposed elementary school. DTSC determined no further action after Preliminary Endangerment Assessment. Refer to Table 3for more information.
		Southern Adjacent – Haz Gen, HHSS, Hist Tank, IHW Ventura (Graham Ranch at 4850 N. Ventura Ave.)	No	Handled/stored hazardous materials and/or generated hazardous waste; no releases reported Reported two 125-gallon farm motor vehicle fuel tanks on property in 1988; no releases reported

Site	Listings	Database Reference/Address	Finding Identified	Comment
		Southwest Adjacent – **CalSites**, **CERCLIS**, **Cleanup Sites**, Delisted County, Emissions, Envirostor, **HAZR Ventura**, HHSS, Hist Tank, **HLUFT Ventura**, **LUST**, RCRA Non Gen, **SEMS**, UST, UST Inactive Ventura, UST SWEEPS, **VCP** (Palm Road LLC and USA Petrochem at 4777 Crooked Palm Rd.)	Yes	Previous agricultural chemical plant from at least 1953 to 1970s. A petroleum refinery was constructed around 1975 and processing ceased in 1984. Refer to Table 3 for more information.
		Western Adjacent – **Cleanup Sites** (Tri-State Oil Co. at 4704 Crooked Palm Rd.)	Yes	Refer to Table 3 for more information.
		Western Adjacent – CERS Haz, Cupa Ventura, IHW Ventura (AT&T Mobility – Foster Park 5017 Crooked Palm Rd.)	No	Handled/stored hazardous materials and/or generated hazardous waste; no releases reported
Orphan Listings	No	N/A	No	N/A
NPL Sites	No	N/A	No	N/A

Notes: Site names/addresses are listed as reported by ERIS.

Listed regulatory database abbreviations are defined in Appendix C.

Bold – Release database

Findings are discussed in more detail in Table 3.

3.2.2 Nearby Release Sites within 1/3 Mile

Database Summary

In addition to the adjacent listed sites described above, the database search identified nine release sites within 1/3 mile of the subject property. Regulatory agency files reviewed for the nearby release sites identified within 1/10 mile and that have potential to impact the subject property are further discussed in Table 3.

Agency Records

Agency records for the nearby release sites that were identified with the potential to impact the subject property were reviewed online at GeoTracker/EnviroStor, and are summarized in Table 3.

In addition, Rincon reviewed the database report and online resources to identify nearby known or suspect contaminated sites that have the potential for contaminated vapor originating from the nearby sites to migrate beneath the subject property. Based on ASTM E2600-15, *Standard Guide for Vapor Encroachment Screening on Property Involved in Real Estate Transactions*, the following search distances were used to determine if contaminated soil vapors from a nearby known or suspect contaminated site have the potential to be migrating beneath the subject property:

- Recommended minimum search distance for nearby known or suspect contaminated sites:
  - Petroleum hydrocarbons – 1/10 mile (528 feet)
  - Other COCs – 1/3 mile (1,760 feet)

- Critical distance for vapor intrusion concern at the subject property based on the presence of contaminated soil, soil vapor, and/or groundwater plumes:
  - Petroleum hydrocarbons – 30 feet
  - Other COCs – 100 feet

Summaries of sites considered to be a potential vapor intrusion concern to the subject property are included in Table 3.

Table 3 Summary of Release Sites Located within 1/10 Mile (Petroleum Hydrocarbons) or 1/3 Mile (Other COCs) and that have Potential to Impact the Subject Property

Site Name/ Address	Listed Regulatory Databases	Case Status	Soil/ Soil Vapor/ Groundwater Impacts and COCs	Depth to Groundwater/ Groundwater Flow Direction	Release Distance and Direction from Subject Property	Potential Vapor Intrusion Concern	Potential Impacts to Soil, Soil Vapor, and/or Groundwater at the Subject Property
Westside Elementary School 4584 N. Ventura Ave.	**CalSites**, Envirostor, SCH	No Further Action (7/27/2001)	Soil – Metals, organochlorine pesticides Soil vapor – none Groundwater – unknown	18 – 32 feet below grade (1998)	Approx. 600 feet south	No	No, based on distance to the subject property.
Palm Road LLC and USA Petrochem 4777 Crooked Palm Rd.	**CalSites**, **CERCLIS**, **Cleanup Sites**, Delisted County, Emissions, Envirostor, **HAZR Ventura**, HHSS, Hist Tank, **HLUFT** Ventura, **LUST**, RCRA Non Gen, **SEMS**, UST, UST Inactive Ventura, UST SWEEPS, **VCP**	Voluntary Agreement Program case – land use restrictions as of 11/25/2024 3 LUST cases – closed (1991, 2012) 3 Cleanup program cases – closed (2009, 2010, 2012)	Groundwater and soil – Metals, TPHg, TPHd, VOCs, SVOCs, PCBs Soil Vapor – VOCs, TPHg	8 – 18 feet, southwest (2010)	Approx. 400 feet west	No	No, based on groundwater flow direction and distance to the subject property.
Tri State Oil Co. 4704/4705 Crooked Palm Rd	**Cleanup Sites, LUST**	LUST case – closed (10/17/1995) Cleanup Program case – closed (10/21/1996)	Groundwater – TPHg, TPHd, TPHmo Soil and soil vapor – unknown	Unknown	Unknown (site is approx. 400 feet west)	No	No, based on distance to the subject property. Likely investigated concurrently with USA Petrochem cases (see above).
5000 Block Ventura Ave.	**HAZR Ventura**	Unknown	Unknown	Unknown	Unknown	Yes	Yes, based on lack of information available.

Site Name/ Address	Listed Regulatory Databases	Case Status	Soil/ Soil Vapor/ Groundwater Impacts and COCs	Depth to Groundwater/ Groundwater Flow Direction	Release Distance and Direction from Subject Property	Potential Vapor Intrusion Concern	Potential Impacts to Soil, Soil Vapor, and/or Groundwater at the Subject Property
Coil Tubing and Nitrogen / Camco / Carters Sandblasting 5100 N. Ventura Ave.	**CalSites**, **CERCLIS**, CERCLIS NFRAP, **Cleanup Sites**, Delisted Cleanup, Delisted County, Emissions, **Envirostor**, IHW Ventura, RCRA Non Gen, SEMS Archive, Waste Discharge	Historical Cleanup Program case – no further action (11/18/1997) Cleanup Program case – open, inactive (1/29/2015)	Unknown	Unknown	Unknown (site is approx. 580 feet northwest)	No	No, based on distance to the subject property.

Site names/addresses are listed as reported by ERIS
Listed regulatory database abbreviations are defined in Appendix C
Bold – Release database
bgs – Below ground surface
COC – Contaminant of concern
PCBs – Polychlorinated biphenyls
SVOC – Semi-volatile organic compound
TPHg – Total petroleum hydrocarbons as gasoline
TPHd – Total petroleum hydrocarbons as diesel
TPHmo – Total petroleum hydrocarbons as motor oil
TPH – Total petroleum hydrocarbons
VOC – Volatile organic compound

3.3 Review of Other Government Records

County, oil well/field, hazardous material pipeline, and/or PFAS records reviewed for the subject property are summarized below in Table 4.

Table 4 Summary of Other Government Records Reviewed

Source	Database Name	Finding Identified	Comments
County of Ventura	County of Ventura Environmental Health Division (EHD) Online Records (EHD 2025)	Yes	Records were reviewed on the EHD online database on January 28, 2025, and included records for a two-gallon petroleum PCB release from a pole-top transformer on September 23, 2011 at the subject property. The subject property was not listed on any other online EHD databases.
California Geologic Energy Management Division (CalGEM)	Well Finder (CalGEM 2025)	No	The southern portion of the subject property is located within the Ventura oil and gas field; however, no oil wells are located on the subject property or adjacent properties, or within 0.25 mile of the subject property.
United States Department of Transportation (USDOT)	National Pipeline Mapping System (NPMS) Public Map Viewer (USDOT 2025)	No	No natural gas transmission pipelines or hazardous liquid pipelines are located on the subject property or adjacent properties. Additionally, no pipeline-related accidents or incidents are mapped within 0.25 mile of the subject property.
State Water Resources Control Board (SWRCB)	California PFAS Investigations (SWRCB 2025b)	No	There are no current airport, chrome plating, DoD, landfill, publicly owned treatment works facilities, or bulk fuel storage terminals and refineries with PFAS orders listed as located within 0.5 mile of the subject property.
SWRCB	GeoTracker PFAS Map (SWRCB 2025c)	Yes	Perfluorooctanoic acid (PFOA) was detected in Ojai Valley Wastewater Treatment Plant effluent located approximately 0.9 mile northwest of the subject property on December 7, 2021. The effluent contained PFOA at concentrations greater than SWRCB notification and response levels. PFOA and perfluorooctane sulfonic acid (PFOS) were not detected above laboratory reporting limits in the Ventura River Water District drinking water wells located approximately 7 miles northwest of the subject property on October 15, 2019.

4 Historical Records

4.1 Methodology

The historical records review completed for this Phase I ESA includes the sources detailed in Table 5 and the following sections. Copies of the historical resources reviewed are included in Appendix B. The following sections provide summaries of the historical use information available for the subject property and adjacent properties.

Table 5 Summary of Historical Sources Reviewed

Historical Source	Historical Source Years Reviewed	Date Reviewed
Aerial Photographs (ERIS)	1926, 1938, 1947, 1959, 1967, 1970, 1980, 1984, 1994, 2003, 2004, 2005, 2009, 2010, 2012, 2014, 2016, 2018, 2020, 2022	February 25, 2025
City Directories (ERIS)	1926, 1930, 1934, 1938, 1941-42, 1946, 1948-1949, 1952, 1956, 1959, 1962, 1966, 1972, 1975, 1980, 1985, 1991, 1996, 2001, 2003, 2006, 2008, 2012, 2016, 2020, 2023	February 25, 2025
Sanborn Fire Insurance Maps (ERIS)	None available	Not Applicable (N/A)
Topographic Maps (ERIS)	1904, 1941, 1951, 1967, 2015, 2018, 2022	February 25, 2025
Building Permit Records	Not reviewed due to sufficient information from other historical sources	N/A
Other Historical Sources	Not reviewed due to sufficient information from other historical sources	N/A

4.2 Summary of Subject Property Historical Uses

A summary of the historical uses of the subject property is provided in Table 6.

Table 6 Summary of Historical Uses of Subject Property

Land Use	Earliest Use Date	Comments
Undeveloped / Vacant	1904	Undeveloped/vacant land
Agricultural/ Vacant	1926	**Orchards** in the southwestern portion, remainder is undeveloped/vacant land
Agricultural/ Residential	1959	**Orchards** in the southwestern portion, at least two residential/agricultural buildings in the southwestern corner, one water tank in the northern portion (three tanks by 1967, all three tanks removed by 2004), remainder is undeveloped/vacant land

Notes: Site names/addresses are listed as reported by the source

Bold listings indicate land uses with the potential to impact the subject property

4.3 Summary of Adjacent Properties Historical Uses

A summary of the historical uses of adjacent properties is provided in Table 7.

Table 7 Summary of Historical Uses of Adjacent Properties

Adjacent Property Direction	Land Use	Earliest Use Date	Comments
Northwest	Undeveloped / Vacant	1904	Undeveloped/vacant land, two residential/agricultural buildings west of orchards
	Agricultural	1926	Orchards, at least two residential/agricultural buildings west of orchards, two water tanks east of orchards
	Agricultural	1938	Orchards, at least three residential/agricultural buildings west of orchards (intermittent stream recorded in 1951 through orchards), two water tanks east of orchards
	Residential	1959	Residential housing tract and two water tanks east of development
	Residential	1967	Residential housing tract
North	Undeveloped / Vacant	1904	Undeveloped/vacant land
East	Undeveloped / Vacant	1904	Undeveloped/vacant land
South	Undeveloped / Vacant	1904	Undeveloped/vacant land with intermittent stream
	Agricultural	1926	Orchards, one residential/agricultural building west of the orchards, southern intermittent stream; additional building by 1938
	Residential / Vacant	2012	Two residential/commercial buildings west of vacant land, southern intermittent stream
West[1]	Residential	1904	A few residential buildings, light duty road
	Agricultural / Residential	1926	Orchards west of light duty road, a few residential/agricultural buildings
	Agricultural / Residential	1941	Orchards, multiple residential/agricultural buildings, and **Highway 399**; additional buildings by 1951
	Agricultural / Industrial	1959	**Chemical manufacturing facility** (4777 Crooked Palm Road), orchards, residential/agricultural buildings, and **Highway 399** (became **Highway 33** by 1967)
	Residential / Industrial	1975	**Industrial oil facility** (4777 Crooked Palm Road), residential/industrial buildings, and **Highway 33**
	Residential	2016	Residences, **Highway 33**
Central	Undeveloped / Vacant	1904	Undeveloped/vacant land
	Industrial	2003	One water tank with access road

Notes: Site names/addresses are listed as reported by the source

Bold listings indicate land uses with the potential to impact the subject property

[1] - Western adjacent properties are only partially depicted in aerial photographs

4.4 Gaps in Historical Sources

Two gaps of greater than 5 years were identified in the historical records reviewed, from 1904 to 1926 and from 1985 to 1991. These gaps are considered insignificant because the subject property use appears to be similar prior to and following the gaps.

5 Interviews

Rincon performed interviews regarding the subject property and surrounding areas. The purpose of the interviews was to discuss current and historical conditions and to obtain information indicating the presence of RECs in connection with the subject property.

Owner/Site Manager	Jena Meyerstein, trustee with Meyerstein Trust, completed the Owner Questionnaire on February 7, 2025. A copy of the completed questionnaire is included in Appendix A. The property owner presented the following information regarding hazardous material and petroleum hydrocarbon storage and waste generation at the subject property/nearby properties. ▪ Potential presence of pesticides / herbicides due to crop management (orchards) on the subject property The property owner indicated that they are unaware of the presence of industrial drums, storage tanks (above or below ground), fill dirt, pits, ponds, lagoons, sumps, clarifiers, solvent degreasers, stained soil, vent pipes, fill pipes, or access ways, stained surfaces, private wells, non-public water systems, transformers, capacitors, or hydraulic equipment, or records indicating the presence of PCBs at the subject property. The property owner indicated that they are not aware of any pending, threatened, or past litigation or administrative proceedings relevant to hazardous substances or petroleum products in, on, or from the subject property. In addition, they are not aware of any notice from any government entity regarding any possible violation of environmental laws or possible liability relating to hazardous substances or petroleum products at the subject property.
Occupants	The property manager, Tim (surname unknown), was interviewed during the February 19, 2025 site reconnaissance. Information provided during this interview is summarized in Section 6.
Local Government Officials	Rincon contacted local government officials (i.e., regulatory agencies) for records pertaining to the subject property and/or adjacent properties as summarized in Section 3.2.1.
Others	Rincon did not attempt to interview neighboring property owners or others as part of this Phase I ESA.

6 Site Reconnaissance

Rincon performed a reconnaissance of the subject property on February 19, 2025 accompanied by Tim (surname unknown), property manager. The purpose of the reconnaissance was to observe existing subject property conditions and to obtain information indicating the presence of RECs in connection with the subject property.

6.1 Methodology and Limiting Conditions

The site reconnaissance was conducted by:

1. Observing the subject property from public thoroughfares,
2. Observing the adjacent properties from public thoroughfares,
3. Walking the subject property,
4. Observing the exterior of the structures,
5. Backtracking to correlate exterior features with interior features, as necessary, and
6. Observing the subject property from nearby roads and paths.

Because of the large size of the subject property and the undeveloped nature of some portions, the northern and eastern portions of the subject property were viewed generally from adjacent roads. Our observation of the subject property was limited to the exterior of the onsite residential buildings; only the interior of the barn was accessed.

6.2 General Subject Property Information

Table 8 summarizes information pertaining to the subject property.

Table 8 Subject Property Characteristics

Property Characteristic	Description
Subject Property Address(es)	4884 North Ventura Avenue, Ventura, California
Historical Subject Property Address(es)	N/A
Assessor's Parcel Number(s)/Acreage	063-0-110-065, -035, -090, -145/ 83 acres
Subterranean Features	N/A
Current Subject Property Use	Residential and agricultural (orchard)
Current Owner of Subject Property	Meyerstein Trust
Current Tenant(s) of Subject Property	Security and residents

Table 9 provides a summary of descriptions of structures, roads, and other improvements on the subject property.

Table 9 General Subject Property Information

Current Use of the Subject Property/ Adjacent Properties	The subject property is currently in use as a single-family residence and an avocado orchard. A majority of the subject property is undeveloped land. Adjacent properties include residences and vacant/undeveloped land.
Past Use of the Subject Property/ Adjacent Properties	Based on the site reconnaissance, past uses of the subject property and adjacent properties are not readily apparent.
Past Uses in the Surrounding Areas	Past uses of the surrounding area are not readily apparent based on the site reconnaissance.
Onsite Structures and Other Improvements	One residential building, barn, corral, and sheds/storage containers are located in the southwestern corner of the property. A chain-link fence was noted to partially surround the vicinity of the buildings in the southwestern corner of the property.
Roads	A few unpaved roads are located on the subject property. Access to the subject property is available from a driveway on North Ventura Avenue.
Potable Water Supply	Ventura Water currently supplies potable water to the subject property.
Sewage Disposal System	The subject property is connected to the Ventura Water sewer system or a private septic system.
Stormwater Runoff	Surface water runoff was not apparent at the subject property as it is unpaved, although likely moves toward North Ventura Avenue in accordance with subject property topography.

6.3 Current Adjacent Land Uses

The current adjacent land uses are described in Table 10 and depicted on Figure 3.

Table 10 Current Uses of Adjacent Properties

Area	Use
Northwestern Properties	Residential
Northern Properties	Undeveloped/vacant land
Eastern Properties	Undeveloped/vacant land
Southern Properties	Residential
Western Properties	North Ventura Avenue, Norway Drive, a residence, and Highway 33 followed by Crooked Palm Road and vacant land
Central Properties	One water reservoir with access road

Figure 3 Adjacent Land Use

6.4 Site Reconnaissance Observations

Table 11 provides details regarding the exterior observations noted during the site reconnaissance. Photographs 1 through 20 are shown below.

Table 11 Exterior Observations

Item	Observed	Photograph Number	Description
Hazardous Substances and Petroleum Products in Connection with Identified Uses	Yes	5, 8, 9	Outside Barn – Smudge pot (appears to be used as an outdoor heater), discarded pressurized cylinders Main Barn – 5-gallon container of gasoline, multiple 1- and 5-gallon paint cans Rincon did not observe indications of releases from these containers.
Aboveground or Underground Storage Tanks	Yes	6, 7	Orchard – One trailer-mounted approximately 1,000-gallon aboveground storage tank (AST) of unknown contents Orchard – One approximately 250-gallon AST of unknown contents resting on the ground The tanks were rusted and appeared in poor condition; however, indications of release were not observed.
Odors	No	Not Applicable (N/A)	None noted
Pools of Liquid	No	N/A	None observed
Drums	No	N/A	None observed
Hazardous Substances and Petroleum Products Containers Not in Connection with Identified Uses	No	N/A	None observed
Unidentified Substance Containers	No	N/A	None observed
Potential Indications of PCBs	Yes	5, 10	Pole-Mounted Transformers – Along northwestern subject property boundary There was no indication of a release in the vicinity of the transformers. Outside Barn – One hydraulic-operated forklift and tractor Soil beneath equipment was unable to be observed for indications of release
Heating/Cooling Systems	No	N/A	None observed
Stains or Corrosion	No	N/A	None observed
Drains, Clarifiers, and Sumps	No	N/A	None observed
Degreasers/Parts Washers	No	N/A	None observed
Pits, Ponds, and Lagoons	No	N/A	None observed

Item	Observed	Photograph Number	Description
Stained Soil or Stained Pavement	Yes	11	Minor soil and concrete staining near motorized equipment and garages/barn from stored vehicles/equipment
Stressed Vegetation	No	N/A	None observed
Solid Waste/Debris	Yes	12, 13, 14	Barn and Storage Yard – Agricultural and mechanical debris, including old vehicles/automotive parts, tires, machinery, a discarded oil pump jack, and two discarded Gasboy fuel dispensers
Wastewater	No	N/A	None observed
Wells	Yes	15	Irrigation groundwater well along western boundary of subject property
Septic Systems/Effluent Disposal Systems	Yes	16	Potential septic system near on-site residence
Soil Piles	No	N/A	None observed
Fill Material	No	N/A	None observed

7 Evaluation

Rincon has performed a Phase I ESA in conformance with the scope and limitations of ASTM Practice E1527-21 for the Ventura Ranch Farmworker Housing Complex property located at 4884 North Ventura Avenue in Ventura, California. Any exceptions to, or deletions from, this practice are described in Section 7.2 of this report.

7.1 Significant Assumptions, Limitations, Deviations, Exceptions, Special Terms, and Conditions

This work is intended to adhere to good commercial, customary, and generally accepted environmental investigation practices for similar investigations conducted at this time and in this geographic area. No guarantee or warranties, expressed or implied, are provided. The findings and opinions conveyed in this report are based on findings derived from a site reconnaissance, review of an environmental database report, specified regulatory records and historical sources, and comments made by interviewees. This report is not intended as a comprehensive site characterization and should not be construed as such. Standard data sources relied upon during the completion of Phase I ESAs may vary with regard to accuracy and completeness. Although Rincon believes the data sources are reasonably reliable, Rincon cannot and does not guarantee the authenticity or reliability of the data sources it has used. Additionally, pursuant to our contract, the data sources reviewed included only those that are practically reviewable without the need for extraordinary research.

Rincon has not found evidence that hazardous materials or petroleum products exist at the subject property at levels likely to warrant mitigation. Rincon does not under any circumstances warrant or guarantee that not finding evidence of hazardous materials or petroleum products means that hazardous materials or petroleum products do not exist on the subject property. Additional research, including surface or subsurface sampling and analysis, can reduce the County of Ventura Resources Management Agency Planning Division's risks, but no techniques commonly employed can eliminate these risks altogether.

In addition, pursuant to ASTM E1527-21 practice, our scope of services did not include any inquiries with respect to asbestos-containing building materials unrelated to releases into the environment; biological agents; cultural and historic resources; ecological resources; endangered species; health and safety; indoor air quality unrelated to releases of hazardous substances or petroleum products into the environment; industrial hygiene; lead-based paint unrelated to releases into the environment; lead in drinking water; mold or microbial growth conditions; polychlorinated biphenyl (PCB)-containing building materials (e.g., interior fluorescent light ballasts, paint, and caulk); naturally-occurring radon; regulatory compliance; substances not defined as hazardous substances (including some substances sometimes generally referred to as emerging contaminants) unless or until such substances are classified as a CERCLA hazardous substance; and wetlands.

7.2 ASTM Deviations

Deviations from ASTM E1527-21 practice were not encountered during the completion of this Phase I ESA. An environmental lien search was not completed as part of this assessment; however, one was requested from the user.

7.3 Significant Data Gaps

No significant data gaps were identified during the preparation of this report.

Deviations that could result in data gaps were identified during the preparation of this report:

- Inability to inspect the interior of the onsite residence and residential garage

This deviation is not considered a significant data gap.

7.4 Findings, Opinions, Conclusions, and Recommendations

This assessment has revealed environmental concerns in connection with the subject property, including a REC associated with the current and former agricultural use of the subject property, and Notable Findings associated with stored equipment and ASTs, potential asbestos-containing materials (ACM) and lead-based paint (LBP), the adjacent highway, PFAS reported in nearby effluent, and a nearby release site with no information available. To evaluate the potential impact to the subject property in connection with the REC and Notable Findings identified, we recommend conducting a subsurface investigation in areas planned for ground disturbance, preparing a Soil Management Plan, conducting an ACM and LBP survey, and proper removal and offsite disposal of the stored equipment and ASTs.

The findings, opinions, conclusions, and recommendations of this Phase I ESA are detailed in Table 12.

Table 12 Findings, Opinions, Conclusions, and Recommendations

Finding	Opinion	Conclusion	Recommendation
Current and former agricultural use of the subject property	According to the historical resources reviewed, the subject property appears to have been used for agricultural purposes as an orchard from approximately 1926 to present. During the site reconnaissance, active orchards were observed on the subject property. Agricultural land use is typically associated with the use of pesticides.	REC	Subsurface investigation in areas planned for ground disturbance
Stored vehicles, equipment, and solid waste, including ASTs with unknown contents on the subject property	During the site reconnaissance, various stored vehicles, equipment, machinery, and solid waste were observed in the southwestern corner of the subject property near the barn. Minor soil and concrete staining was observed in these areas. Additionally, two abandoned ASTs were observed within the orchard area on the subject property. Indications of releases were not observed in the vicinity of these features.	Notable Finding	Proper removal and offsite disposal prior to redevelopment Soil Management Plan
Potential asbestos-containing materials (ACM) and lead-based paint (LBP) at the subject property	Based on the age of the onsite structures (constructed as early as 1959), ACM and LBP may be present in building materials at the subject property.	Notable Finding	ACM and LBP survey prior to demolition or renovation of onsite structures
Potential presence of aerially deposited lead (ADL) in shallow soil on the subject property	According to the historical resources reviewed, Highway 33 was constructed adjacent to the west of the subject property by 1941 (originally identified as Route 399). Elevated concentrations of lead may exist in soils along older roadways as a result of ADL from the historical use of leaded gasoline in motor vehicles. Based on the presence of Highway 33 adjacent to the west of the subject property (approximately 220 feet away) during the time period that leaded gasoline was used in motor vehicles (1920s to 1992; DTSC 2016), there is a potential for elevated concentrations of ADL to be present in onsite shallow soil. However, elevated concentrations of lead are typically found in the top 6 inches and within 20 feet of the roadways, with maximum concentrations within approximately 10 feet (DTSC 2016).	Notable Finding	None
Reported PFAS in effluent within one mile of the subject property	According to the California Statewide Drinking Water System Quarterly Testing Results online Public Map Viewer (Table 4), PFOA was detected in Ojai Valley Wastewater Treatment Plant effluent samples collected approximately 0.9 mile from the subject property at concentrations greater than their respective SWRCB notification and response levels. However, PFOA and PFOS were not detected above laboratory reporting limits in Ventura River Water District drinking water wells approximately 7 miles from the subject property. It is unknown if concentrations of PFAS have an impact on water quality with Ventura Water's service area. For information regarding potable water quality provided to the subject property, contact Ventura Water.	Notable Finding	Contact Ventura Water
Nearby release site with no information available	According to the database report, a nearby property at the 5000 block of North Ventura Avenue was listed on a release database. No additional information pertaining to the location or type of release was provided by ERIS or available on GeoTracker, EnviroStor, or the EHD online records portal.	Notable Finding	Soil Management Plan

Finding	Opinion	Conclusion	Recommendation
Previous small-quantity releases reported at the subject property	The HAZR Ventura regulatory database indicates that a release of 5-10 gallons of smudge oil due to a standpipe leak occurred onsite in 1990 and a release of two gallons of PCB oil from a pole-top transformer occurred onsite in 2011 and was removed by a contractor. However, the locations of these releases are unknown.	De minimis	Soil Management Plan
Deviation from ASTM Standard	The interiors of the onsite residence and residential garage were not observed during the site reconnaissance.	Deviation resulting in possible data gap	Observe interiors of onsite buildings if evidence of hazardous materials use

9 Signatures of Environmental Professionals

The qualified environmental professionals that are responsible for preparing the report include Andy Nelson and Savanna Vrevich. Their qualifications are summarized in the following section.

"We declare that, to the best of our professional knowledge and belief, we meet the definition of Environmental Professional as defined in 312.10 of 40 CFR 312. We have the specific qualifications based on education, training, and experience to assess a property of the nature, history, and setting of the subject property. We have developed and performed the all appropriate inquiries in conformance with the standards and practices set forth in 40 CFR Part 312."

Signature	Date
Andy Nelson, PG	Director
Name	Title

Signature	Date
Savanna Vrevich	Environmental Scientist

10 Qualifications of Environmental Consultants

The environmental consultants responsible for conducting this Phase I ESA and preparing the report include the individuals listed below, along with a summary of their qualifications.

Environmental Professional Qualifications	X2.1.1 (2) (i) - Professional Engineer or Professional Geologist License or Registration, and 3 years of full-time relevant experience	X2.1.1 (2) (ii) - Licensed or certified by the Federal Government, State, Tribe, or U.S. Territory to perform environmental inquiries	X2.1.1 (2) (iii) – Baccalaureate or Higher Degree from and accredited institution of higher education in a discipline of engineering or science and the equivalent of 5 years of full-time relevant experience	X2.1.1 (2) (iii) – Equivalent of 10 years of full-time relevant experience
Andy Nelson	PG		BS Geology	24 years
Savanna Vrevich			BS Environmental Studies	9 years
Landon Lujan			BS Environmental Earth and Soil Science	3 years

Andy Nelson, PG, is a Senior Geologist and Director of Assessment and Remediation with Rincon Consultants. He holds a Bachelor of Science degree in Geology from the University of California at Santa Barbara and a California Professional Geologist license. Mr. Nelson's responsibilities at Rincon include oversight and implementation of Rincon's assessment and remediation division in addition to providing technical guidance while acting as an advisor on environmental issues. Mr. Nelson has experience conducting Phase I ESAs as well as assessment and remediation of commercial and industrial properties.

Savanna Vrevich is an Environmental Scientist with Rincon Consultants. She holds a Bachelor of Science degree in Environmental Studies from the University of California, Santa Barbara. Ms. Vrevich has experience in working on large-scale, multi-site projects for developers, banks, regulatory agencies, and other public and private clients. Ms. Vrevich's responsibilities at Rincon include management and implementation of Phase I ESAs, Phase II ESAs, Caltrans Initial Site Assessments, and preparation of other environmental reports for a variety of commercial, rural, and industrial properties.

Landon Lujan is an Environmental Scientist with Rincon Consultants. He holds a Bachelor of Science degree in Environmental Earth and Soil Sciences from the California Polytechnic State University of San Luis Obispo. Mr. Lujan's responsibilities at Rincon include implementation of Phase I and Phase II Environmental Site Assessments, sampling of soil, groundwater, surface water, and air, as well as preparation and analysis of data and reports for a variety of commercial, rural, and industrial clients.

INTENTIONALLY LEFT BLANK

Executive Summary

The Ventura Ranch Farmworker Housing Project (Project) is proposed in Ventura, California. The Project site consists of four (4) development parcels that total approximately 82.92 acres. The Project proposes to develop 328 housing units for farm workers that range in size from approximately 570 square feet to approximately 1,095 square feet. The Project will also include community spaces, a maintenance building, as well as open space and agricultural land. The Ventura Ranch Farmworker Housing Project is accessed via two ingress/egress points along Ventura Avenue. The Project also provides a gated emergency vehicle access connection to Floral Drive in the Norway Tract / Valley Vista community to the north.

The Project site is designated a Very High Fire Hazard Severity Zone (VHFHSZ) in a Local Responsibility Area (LRA). As a requirement of development in a designated VHFHSZ, as described further in the Project's Fire Protection Plan (Dudek 2025), the Project is required to comply with all applicable requirements of the California Building Code (Chapter 7A) and California Fire Code (Chapter 49). These requirements include enhanced construction features (e.g., Class A roof, vents, interior sprinklers, etc.) for ignition resistance, emergency access, and defensible space that work together to provide a systematic approach to fire protection.

Given the Project's setting in a VHFHSZ, the most likely cause of evacuation from the Project site is wildland fire. The purpose of this WES is to evaluate the Project's consistency with relevant emergency evacuation plans and emergency response plans, disclose the prevention and minimization regulations and measures applicable to the Project, and determine evacuation times for the existing and post-Project conditions, as well as provide recommendations for emergency preparedness that include information and resources to increase occupant preparedness for wildfire evacuations. Herein, information is provided addressing evacuation organization, planning and preparedness, evacuation routes, contingencies, and other related topics.

Evacuation routes available to the Project occupants include State Route (SR-) 33, North Ventura Avenue, Crooked Palm Road, Shells Road, and Ventura Freeway U.S. Route 101. The Project also proposes an emergency vehicle access (EVA) road that connects the Project site north to the Valley Vista Community, which would provide a secondary north/south evacuation route via Floral Drive. As part of the WES, evacuation time modeling was prepared to evaluate potential Project impacts to existing evacuation conditions. Three scenarios analyzed the time needed to evacuate the existing land uses with and without Project populations. Using conservative assumptions, these scenarios considered (1) existing land uses, (2) Project only (3) existing land uses with Project.

The key finding of this study is that the Project would not conflict with an emergency evacuation plan or emergency response plan, and impacts would be less than significant without mitigation. Further, the available roadway capacity is sufficient to safely accommodate the number of evacuating vehicles within the relevant areas with and without the Project development. Project impacts would be less than significant as this study demonstrates that evacuation times would be reasonable and would allow for safe evacuations to be conducted under all scenarios.

The Project would provide a new north/south evacuation route that would provide secondary access for the Project as well as the community to the north. Further, the Project does not propose to cut off or otherwise modify existing evacuation routes. In an evacuation or emergency scenario, adequate emergency access would be maintained. Considering these facts and others discussed herein, the Project would not expose people to a significant risk of loss or death involving wildland fires related to evacuation, would not interfere with evacuation response planning, and would not result in inadequate emergency access.

INTENTIONALLY LEFT BLANK

1 Introduction

This Wildfire Evacuation Study (WES) was prepared based on guidance from and is consistent with Ventura County Operational Area (OA) EOP (2021) and the Ventura County All Hazards Evacuation Plan (2024), which provides further evacuation specific guidance. Due to the Project's vicinity to the City of Ventura, this WES also considers the City's Emergency Operations Plan (EOP) (2021). Complete copies of these plans can be downloaded at the following links:

County EOP and All Hazards Evacuation Plan

https://www.readyventuracounty.org/county-plans/

City EOP

https://www.cityofventura.ca.gov/2156/Emergency-Services

1.1 Project Description

Project Location

The Ventura Ranch Project (Project) is in the unincorporated Ventura County, north of the City of Ventura. The Project is in the City of Ventura's sphere of influence but not immediately adjacent to a city boundary. The overall Ventura Ranch development is comprised of approximately 82.92 acres of land located near the agricultural regions of the Oxnard Plain. The Project site is immediately south of the Valley Vista community (Figure 1, Project Vicinity). Surrounding land uses include residential and commercial use to the north and south, open land to the east, and agricultural and open land to the west. Access to Project site is provided by two access points on Ventura Avenue.

Project Summary

The Project proposes a residential development to provide critical farmworker housing in Ventura County. The Project would construct 328 apartments that range in size from approximately 570 square feet to approximately 1,095 square feet and 565 parking spaces. Additionally, the Project will provide community recreational spaces such as a basketball court, a garden, walking paths, and playgrounds (Figure 2, Project Site Plan).

1.2 Applicable Regulations, Standards, and Planning Tools

1.2.1 Federal

1.2.1.1 Disaster Mitigation Act

The Disaster Mitigation Act of 2000 requires that a state mitigation plan, as a condition of disaster assistance, add incentives for increased coordination and integration of mitigation activities at the state level through the establishment of requirements for two different levels of state plans: "Standard" and "Enhanced." States that develop an approved Enhanced State Plan can increase the amount of funding available through the Hazard Mitigation Grant Program. The Disaster Mitigation Act also established a new requirement for local mitigation plans.

1.2.1.2 National Incident Management System (NIMS)

The National Incident Management System (NIMS) guides all levels of government, nongovernmental organizations, and the private sector to work together to prevent, protect against, mitigate, respond to, and recover from incidents. NIMS provides community members with a shared vocabulary, systems, and processes to successfully deliver the capabilities described in the National Preparedness System. The National Preparedness System is a Presidential Policy Directive establishing a common goal to create a secure and resilient nation associated with prevention, protection, mitigation, response, and recovery to address the greatest risks to the nation. One core area is fire management and suppression.

NIMS defines operational systems that guide how personnel work together during incidents.

1.2.1.3 Pet Evacuation and Transportation Standards Act

The Pets Evacuation and Transportation Standards Act of 2006 amends the Stafford Act, and requires evacuation plans to take into account the needs of individuals with household pets and service animals, prior to, during, and following a major disaster or emergency.

1.2.2 State

1.2.2.1 Fire Hazard Severity Zones

To assist each fire agency in addressing its responsibility area, California Department of Forestry and Fire Protection (CAL FIRE) uses a severity classification system to identify areas or zones of severity for fire hazards within the state. CAL FIRE's adopted maps identified the fire hazard severity zones for State Responsibility Areas and identify Very High Fire Hazard Severity Zone (VHFHSZ) for Local Responsibility Areas (LRAs). However, on March 24, 2025, the Office of the State Fire Marshal (OSFM) released the 2025 Recommended Local Responsibility Area Fire Hazard Severity Zone Map for Southern California. The draft map is currently under review and has not yet been adopted; therefore, the content of the map is subject to change. The Project Site is designated as a VHFHSZ located within a LRA.

1.2.2.2 California Wildland-Urban Interface Code

On September 20, 2005, the California Building Standards Commission approved the Office of the State Fire Marshal's emergency regulations amending the California Building Code (CBC) (California Code of Regulations [CCR] Title 24, Part 2). Section 701A of the CBC includes regulations addressing materials and construction methods for exterior wildfire exposure and applies to new buildings located in State Responsibility Areas or Very High Fire Hazard Severity Zones in Local Response Areas.

1.2.2.3 California Fire Code

The 2022 California Fire Code (CCR Title 24, Part 9) establishes regulations to safeguard against the hazards of fire, explosion, or dangerous conditions in new and existing buildings, structures, and premises. The Fire Code also establishes requirements intended to provide safety for and assistance to firefighters and emergency responders during emergency operations. The Fire Code includes regulations regarding fire-resistance-rated construction, fire protection systems such as alarm and sprinkler systems, fire services features such as fire apparatus access roads, means of egress, fire safety during construction and demolition, and wildland-urban interface areas.

1.2.2.4 California Emergency Services Act

The California Emergency Services Act (California Government Code Section 8550, et seq., provides for the creation of an Office of Emergency Services, assign and coordinate functions and duties to be performed during an emergency, facilitate mutual aid, and assign resources (including manpower and facilities) throughout the state for dealing with any emergency that may occur.

1.2.2.5 California Office of Emergency Services

The California Office of Emergency Services (OES) is responsible for the coordination of overall state agency response to disasters. Assuring the state's readiness to respond to, recover from all hazards and assisting local governments in their emergency preparedness, response, recovery, and mitigation.

1.2.2.5.1 Standardized Emergency Management System (SEMS)

The Standardized Emergency Management System (SEMS) is the cornerstone of California's emergency response system and the fundamental structure for the response phase of emergency management. The system unifies all elements of California's emergency management community into a single integrated system and standardizes key elements. SEMS incorporates:

- Incident Command System - A field-level emergency response system based on management by objectives.
- Multi/ Inter-agency coordination - Affected agencies working together to coordinate allocations of resources and emergency response activities.
- Mutual Aid - A system for obtaining additional emergency resources from non-affected jurisdictions.
- Operational Area Concept - County and its sub-divisions to coordinate damage information, resource requests and emergency response.

1.2.2.6 Attorney General's Guidance

The California Office of the Attorney General issued (October 2022) guidance (Guidance) outlining the Attorney General's recommendations for "best practices" for analyzing and mitigating wildfire impacts of development projects under the California Environmental Quality Act (CEQA). The Guidance is intended to help local governments' evaluation and approval considerations for development projects in fire-prone areas, and to help project design in a way that minimizes wildfire ignition and incorporates emergency access and evacuation measures. Importantly, the Guidance does not impose additional legal requirements on local governments, nor does it alter any applicable laws or regulations.

The Guidance states that evacuation modeling and planning should be considered for certain projects located in high and very high FHSZs; as projects in these areas have the potential to present an increased risk of ignition and/or evacuation impacts. The Guidance encourages evacuation modeling and planning prior to project approval to provide greater flexibility regarding design modifications if the evaluation demonstrates such changes are required.

The Project is in an area designated as a VHFHSZ within a LRA and is adjacent to open space areas. However, the Project proposes a design that minimizes fire, includes two separate access roads and is proximate to major transportation corridors such as SR-33 and North Ventura Avenue. This Wildfire Evacuation Study, which includes modeling and the analysis of several evacuation scenarios that address existing conditions, cumulative projects and/or the project, incorporates elements and performs analysis contemplated by the Guidance.

The Guidance provides that evacuation modeling and analysis should include the following:

- Evaluation of the capacity of roadways to accommodate project and community evacuation and simultaneous emergency access.
  - Existing and future roadway capacities are analyzed in Section 4 of this Wildfire Evacuation Study.
- Assessment of the timing for evacuation.
  - Analysis of evacuation timing is detailed in Section 4.3.
- Identification of alternative plans for evacuation.
  - Alternative plans for evacuation (e.g., shelter-in-place as discussed in Section 2.4.4) would be feasible due to the high ignition resistance level of Project structures.
- Evaluation of the Project's impacts on existing evacuation plans.
  - Existing evacuation plans do not exist for the area so this element does not apply.
- Consideration of the adequacy of emergency access, including the Project's proximity to existing fire services and the capacity of existing services.
  - As disclosed in Section 4, Evacuation Road Network, emergency access is provided in a manner consistent with the fire code requirements.
- Traffic modeling to quantify travel times under various likely scenarios.
  - This Wildfire Evacuation Study conducted simulations using Vissim, a microscopic, multimodal traffic flow modeling software used to simulate different traffic conditions, such as drivers' behaviors during an evacuation. In Vissim simulations, roadway capacity is accounted for and each vehicle in the traffic system is individually tracked through the model and comprehensive measures of effectiveness, such

as average vehicle speed and queueing, are collected on every vehicle during each 0.1 second of the simulation.

1.2.3 Regional and Local

1.2.3.1 Ventura County Multi-Jurisdictional Local Hazard Mitigation Plan

The purpose of the County's Multi-Jurisdictional Hazard Mitigation Plan (Ventura County 2022) is to identify the County's hazards, review and assess past disaster occurrences, estimate the probability of future occurrences, and set goals to mitigate potential risks to reduce or eliminate long-term risk to people and property from natural and human-made hazards.

1.2.3.2 Ventura County Emergency Operations Plan

The 2021 Ventura County Operational Area (OA) Emergency Operations Plan (EOP) describes a comprehensive emergency management system that provides for a planned response to disaster situations associated with natural disasters, technological incidents, terrorism, and nuclear-related incidents. This plan delineates operational concepts relating to various emergency situations, identify components of the Emergency Management Organization, and describes the overall responsibilities for protecting life and property and providing for the overall well-being of the population. The plan also identifies the sources of outside support that might be provided (through mutual aid and specific statutory authorities) by other jurisdictions, state and federal agencies, and the private sector.

1.2.3.3 County of Ventura All Hazards Evacuation Plan

The 2024 All Hazards Evacuation Plan details the County of Ventura's responsibilities for the management of an evacuation response. This plan was created as an annex to the Ventura County Operational Area EOP. This plan can be used in conjunction with the EOP and other annexes and plans designed for the protection of the population. Responsibilities, tasks, and pertinent activities pertaining to a large-scale evacuation within the County are defined. The plan is consistent with SEMS and the Incident Command System, while also integrating local plans, ordinances, and laws.

1.2.3.4 County of Ventura Fire Code

The County of Ventura Fire Code (Ordinance 32 2023) adopts the 2022 California Fire Code with additions, deletions and amendments. Provisions of the California Fire Code are described under State Regulations, above.

1.2.3.5 County of Ventura Building Code

The County's Building Code (elements 101.1.1 through 101.1.4) is intended to regulate the construction of applicable facilities and encompasses (and formally adopts) associated elements of the 2022 California Building Code. Specifically, this includes regulating the erection, construction, enlargement, alteration, repair, moving, removal, demolition, conversion, occupancy, use, height, area and maintenance of all structures and certain equipment therein.

INTENTIONALLY LEFT BLANK

2 Local and Regional Evacuation Planning

Evacuation is defined by the State of California as the organized, phased and supervised withdrawal, dispersal, or removal of civilians from dangerous or potentially dangerous areas and their reception and care in safe areas (Cal OES, 2017). When the threat passes, evacuees can return to their normal activities, or to make suitable alternative arrangements. Evacuation during a wildfire is not typically directed by the fire agency, except in specific areas where fire personnel may enact evacuations on-scene. Local law enforcement has primary responsibility for emergency evacuations. The Project is in Ventura County Fire Department (VCFD) jurisdiction; the closest available fire station is typically dispatched, which would be the Ventura County Fire Department Station 23. Evacuations of the area would be directed by Ventura County Sheriff's Office (VCSO).

Every evacuation scenario will include some level of unique challenges, constraints, and fluid conditions that require interpretation, fast decision making, and alternatives. For example, one roadway incident that results in blockage of evacuating vehicles may require short-term or long-term changes to the evacuation process. Risk is considered high when evacuees are evacuating late, and fire encroachment is imminent. This hypothetical scenario highlights the importance of continuing to train responding agencies, model various scenarios, educate the public, provide contingency plans, and take a very conservative approach to evacuation decision timelines.

Equally as important, the evacuation procedures should be regularly updated with lessons learned from actual evacuation events. The County of Ventura has an All-Hazards Evacuation Plan (2024) as a functional annex to the County EOP. The All-Hazards Evacuation Plan assigns tasks, procedures, and policies to guide large-scale evacuation events within the County. This WES was prepared and is consistent with the County OA EOP's evacuation planning standards and can be integrated into a regional evacuation plan and other pre-plans when and if area officials and stakeholders (CAL FIRE, VCFD, OES, VCSO, and others) complete one.

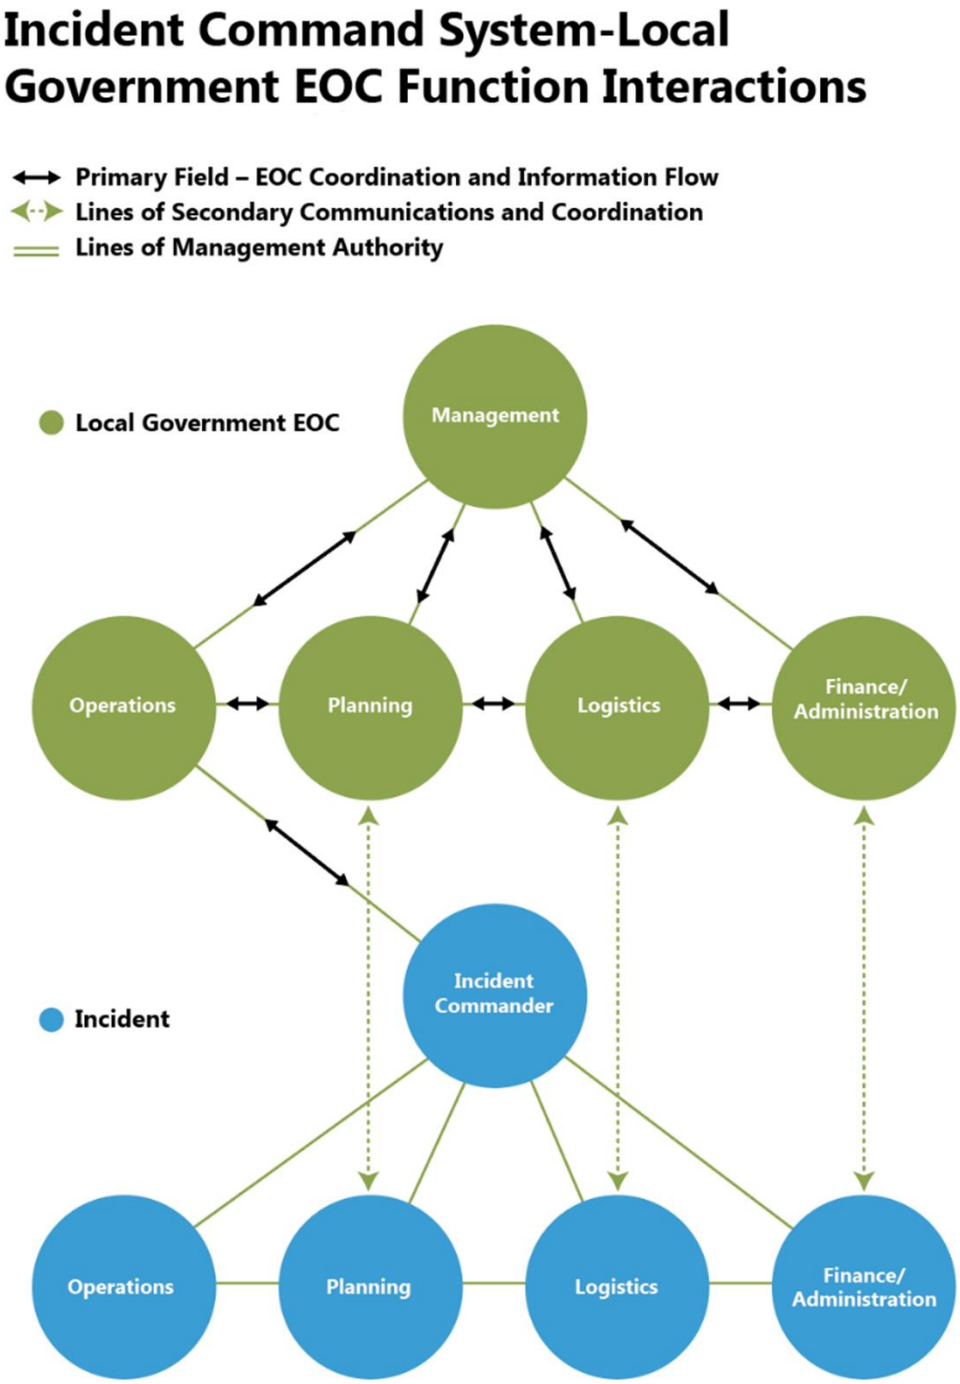
The following sections summarize County emergency operations procedures relevant to an evacuation of the Project as detailed in the County's EOP.

2.1 County Emergency Operations Procedures

To establish a framework for implementing well-coordinated evacuations, the County, like most California emergency operations agencies, has adopted evacuation procedures in accordance with the State of California's SEMS and the Federal NIMS. Large-scale evacuations are complex, multi-jurisdictional efforts that require coordination between many agencies and organizations. Emergency services and other public safety organizations play key roles in ensuring that an evacuation is effective, efficient, and safe.

The County EOP sets forth basic protocols which dictate who is responsible for an evacuation effort and how regional resources may be requested and coordinated. First responders are responsible for determining initial protective actions before Emergency Operations Centers (EOCs) and emergency management personnel have an opportunity to convene and gain situational awareness. Initial protective actions are shared/communicated to local EOCs and necessary support agencies as soon as possible to ensure an effective, coordinated evacuation. Figure 3 summarizes the functional interactions of local government EOCs under the Incident Command System.

Figure 3 - Incident Command System Functions



During a multi-jurisdictional evacuation effort, the VCSO will declare and coordinate and be assisted by other law enforcement and support agencies. Law enforcement agencies, highway/road/street departments, and public and private transportation providers will conduct evacuation operations. Procurement, regulation, and allocation of resources will be accomplished by those designated. Evacuation operations will be conducted by the following agencies:

- Ventura County Sheriff's Office
- City of Ventura Police Department
- Ventura County Fire Department
- County of Ventura Parks Department
- Ventura County Animal Services
- Ventura County Public Works and Transportation Commission
- American Red Cross
- Other City, County, and state agencies, as needed

2.2 Evacuation Objectives

Emergency evacuation operations and notifications are described in the Ventura County All Hazards Evacuation Plan (2024) with the following objectives:

- Move as few people as necessary the shortest distance to safety
- Provide for the safe and effective evacuation of people and animals from an area that poses a threat to their health and safety to a safe area.
- Efficiently use available transportation resources and existing infrastructure to facilitate the movement of people and animals.
- Coordinate and help facilitate the activation of care and shelter services.
- Work collaboratively with local partners to affect an evacuation.
- Support securing evacuated areas until re-entry is possible.
- Ensure re-entry to evacuated areas is safe, feasible and appropriate.

The Ventura County Sheriff's Office acts as the lead agency for evacuations of both the unincorporated areas of Ventura County and the incorporated cities that contract with the Sheriff's Office for services. The Sheriff's Office also serves as the Law Enforcement Operational Area Mutual Aid Coordinator. The VCSO is the lead agency for conducting evacuations within the unincorporated areas within the County of Ventura boundaries, including the Project site. If necessary, Unified Command will assess and evaluate the need for evacuations with cooperating agencies, and VCSO or local law enforcement orders and conducts evacuations according to established procedures, which are outlined in the All Hazards Evacuation Plan. Additionally, as part of the Unified Command, the VCSO or local law enforcement will identify available and appropriate evacuation routes and coordinate evacuation traffic management with the California Department of Transportation, the California Highway Patrol, other supporting agencies, and jurisdictions.

2.3 Evacuation Coordination Process

The decision to evacuate an area is not made lightly and there is a significant impact to public safety and the economy. The following process describes how emergency evacuation decisions within the OA will be coordinated, allowing emergency managers and other supporting response organizations to make collaborative decisions.

The response to an emergency event such as a wildfire will be managed at a local level, with the local jurisdiction being responsible for preparedness, response and recovery. The affected jurisdiction will assess the situation and make the determination on whether to evacuate communities as the need arises, on a case-by-case basis accordance with established plans and procedures. The decision to evacuate will depend entirely upon the nature, scope, and severity of the emergency; the number of people affected; and what actions are necessary to protect the public. Local jurisdictions may activate their EOC and conduct evacuations according to procedures outlined in their EOP. All evacuations from, through, or into a local jurisdiction will be coordinated with that jurisdiction's public safety partners.

Local jurisdictions can request support from the Ventura County OA if an event is beyond their capacity to handle. In these circumstances the Ventura County OA EOC may be activated. Regional coordination is required for any evacuation impacting multiple jurisdictions. The OA EOC may make recommendations on whether a jurisdiction should evacuate and may help coordinate the evacuation effort, if requested by the jurisdiction. The All Hazards Evacuation Plan is automatically activated when an incident occurs requiring an evacuation effort that impacts two or more jurisdictions within the OA or when there is an evacuation in the unincorporated area necessitating response from the County. If the emergency impacts multiple jurisdictions within the OA, all impacted jurisdictions may activate their EOCs, the OA EOC may be activated including the Joint Information Center. The OA EOC will obtain situational awareness to understand the severity of the incident. The Unified Command consisting of fire, law enforcement, and other relevant support agencies will communicate with the OA EOC and emergency management personnel. Other EOC actions include consideration of additional protective measures, public information needs, determination of next steps, and an update schedule for internal and external communications. Emergency public information will be provided to the public in accordance with procedures established in Public Information Plan Annex of the County EOP. The OA EOC may support the evacuation response by coordinating transportation for individuals with disabilities and others with access and functional needs.

2.4 Evacuation Response Operations

An evacuation of any area requires significant coordination among numerous public, private, and community/non-governmental organizations. Wildfire evacuations will typically allow time for responders to conduct evacuation notification in advance of an immediate threat to life safety; giving occupants time to gather belongings and make arrangements for evacuation. Other threats, including wildfires igniting nearby, may occur with little or no notice and certain evacuation response operations will not be feasible (for example, establishing contra flow requires between 24 to 72 hours to be implemented). Every attempt will be made to assist people with safe evacuation, and risk to first responders is an additional important consideration. People are encouraged to evacuate early and to help their neighbors, friends, and family to evacuate if doing so will not cause danger to themselves or others.

2.4.1 Emergency Communications

As demonstrated during large and localized evacuations occurring throughout the County over the past 10 years, an important component to successful evacuation is early assessment of the situation and early notification via managed evacuation declarations. The County utilizes early warning and informational programs to help meet these important factors. Among the methods available to citizens for emergency information are radio, television, social media/internet, neighborhood patrol car, aerial public address notifications, and Reverse 911 or VC Alert. The County instituted VC Alert (a regional notification system that sends telephone notifications to occupants and businesses within areas impacted by, or in danger of being impacted by, an emergency or disaster. VC Alert is used by emergency response personnel to notify at risk occupants and businesses with information on the event and/or actions (such as evacuation, shelter-in-place, gas leak, missing person, etc.) they are advised to implement. The TTY/TDD capable system utilizes the region's database, compiling VC Alert citizen opt-in account registrations, 911 Emergency Service Listing data (residents and business telephone numbers), to contact telephones whether listed or unlisted. Because the system uses the 911 database and local yellow and white pages, most numbers in the system are landlines. If you have a Voice over Internet Protocol (VoIP) or cellular telephone and would like to be notified over that device, or if you would like an email notification, you must register those telephone numbers and/or email address for use by the system to receive voice, text, and email messages.

Should the need arise to evacuate due to a wildfire, notifications will be made to the Project residents through the VC Alert Emergency Notification System, door-to-door notifications from the Sheriff's Office, Wireless Emergency Alerts, and the emergency alert system on televisions and radio stations. Residents can obtain real-time event information from the VC Emergency website on the incident dashboard and map https://emergency.venturacounty.gov/.

- VC Alert: https://member.everbridge.net/1772417038942453/new
- Ready Ventura County: https://www.readyventuracounty.org/vc-alert/

A Wireless Emergency Alert is also a location-based alert but differs from a VC Alert in that you do not need to register. Wireless Emergency Alerts are used by authorized agencies and are broadcast utilizing cell towers. If your cell phone is within a determined radius of the marked hazard, you will receive the notification. These alerts stay active for a set period of time, so it is possible that those just passing by or through may receive the alert as well. A VC Alert differs in that it does not require you to be at your registered location to receive the alert. Therefore, if you register your home address and are away, you will still receive alerts that are directed at your address, regardless of where you are currently located.

The Project site is within the greater Ventura media market, and the media outlets will also be a good source of information via television and radio. Media outlets cover emergency situations and information is disseminated guiding resident response. Commercial media broadcasts emergency information via three radio stations: KVTA 1590 AM, KHAY 100.7 FM, KMLA 103.7 FM (Spanish).

Social media provides another outlet for news:

  - https://www.instagram.com/vcsheriff/
  - https://x.com/venturasheriff

2.4.2 Evacuation Points and Shelters

When the VCSO or IC implements an evacuation order, they coordinate with the Ventura Human Services Agency and the American Red Cross, Ventura County, the EOC, and others to decide on a location to use as a Temporary Evacuation Point (TEP) or shelter. The EOC will utilize the VC Alert system and will notify local television and radio stations; the County will also use social media (e.g., Facebook, X (formerly Twitter)) and will direct evacuees to the established TEPs or shelters, which may include schools or other facilities. TEPs will provide basic needs such as food, water, and restrooms. In addition to designated shelters, other points of temporary refuge may include large, well-known sites such as shopping centers and libraries.

Subject to field decisions by VCSO, possible shelters that could provide short-term refuge for evacuated occupants of the Project. Emergency shelters are opened when at least one overnight stay is necessary. Basic services are provided at emergency shelters, which includes meals, accessible shower facilities, dormitory management, health, and behavioral health services. Some temporary evacuation points may be suitable to be converted into an emergency shelter location, if necessary and available. Possible shelters and assembly areas in the Project vicinity that can provide at least short-term refuge and that would be designated by emergency managers during an evacuation include public schools and recreation centers.

An interactive map of the activated mass care locations will be updated regularly and can be found at:

https://www.arcgis.com/apps/mapviewer/index.html?layers=18c2ee5376f1465e88dd79b384c39e5c.

If there are occupants unable to evacuate and need transportation assistance to get to a TEP or shelter, the VCSO or Incident Command may establish transportation points to collect and transport people without transportation resources to evacuation points. Transportation should be accessible to all populations, including people with disabilities and other access and functional needs.

2.4.3 Pet Evacuations

The Pets Evacuation and Transportation Standards Act of 2006 amends the Stafford Act and requires evacuation plans to consider the needs of individuals with household pets and service animals prior to, during, and following a major disaster or emergency.

The Ventura County OA EOP outlines the process and responsibilities of Ventura County Animal Services, and other agencies to assist in pet evacuations. Ventura County Animal Services provides shelter and care for all types of service/companion animals during emergencies and disasters at shelter locations. Historically the Ventura County Fairgrounds have been a location where owners have brought their animals for safekeeping. Ventura County Animal Services has assisted in numerous calls for assistance during wildfires over the past few decades. Including the 2018 Hill Fire, 2018 Woolsey Fire, 2019 Maria Fire, 2019 Easy Fire, and the 2024 Mountain Fire. At the onset of a wildfire emergency, residents can call Ventura County Animal Services and request emergency rescue to assist. The Emergency Volunteer Rescue Team is an on-call emergency volunteer group established by Ventura County Animal Services which is activated to assist in both livestock and domestic animal evacuations to safe, predetermined locations. Ventura County Animal Services will also provide no-cost boarding to animals whose families were ordered to evacuate.

The Humane Society, as well as other non-profit and volunteer organizations, may assist the Ventura County Animal Services in providing support to residents and their pets during an emergency. The Operational Area EOC Care/Shelter Branch Animals Unit coordinates both large animal evacuations and companion animal support during shelter operations. Temporary animal shelters in Ventura County will be collocated with human shelters, when possible. Addressing pet and livestock evacuation and sheltering procedures guarantees maximum protection of both human and animal health and safety. Emergency resources cannot be expected to perform animal evacuations and transport, these processes must be accomplished by public and private animal service agencies.

In the event temporary emergency small animal shelters need to be activated, the Animal Services Emergency Management Coordinator will contact the Duty Officer to identify potential shelter locations. A Public Information Officer will coordinate with OES and media outlets to broadcast information regarding the location of these shelters.

2.4.4 Shelter-in-Place

Sheltering-in-place is the practice of going or remaining indoors during or following an emergency event. This procedure is recommended if there is little time for the public to react to an incident and when it is safer for the public to stay indoors for a short time rather than travel outdoors. Sheltering-in-place also has many advantages because it can be implemented immediately, allowing people to remain in their familiar surroundings and providing individuals with everyday necessities such as telephone, radio, television, food, and clothing. However, the amount of time people can stay sheltered-in-place is dependent upon availability of food, water, medical care, utilities, and access to accurate and reliable information.

Sheltering-in-place is the preferred method of protection for people that are not directly impacted, in the direct path of a hazard, or it is unsafe to evacuate. The decision to evacuate or shelter-in-place will be made by field command (SEMS field level) and in accordance with existing plans and protocols (County of Ventura 2021).

INTENTIONALLY LEFT BLANK

3 Ventura Ranch Farmworker Housing Project Evacuation Procedures

The following provides a discussion of the types of evacuations that Project occupants could experience (e.g., pre-planned, late-notice, etc.), and Project specific evacuation contingencies and procedures for social aspects of evacuation. For purposes of this WES, the first and most logical choice for all the occupants within the boundaries of the Project is to adhere to the principles and practices of the "Ready, Set, Go!" Program. Under this program, individuals are urged to evacuate as soon as they are notified to do so or earlier if they feel uncomfortable. Directions on evacuation routes will be provided in most cases, but when not provided, occupants of the Project will proceed according to known available routes away from the encroaching fire. Occupants are cautioned not to rely on navigation aid apps, which may inadvertently lead them toward an oncoming fire.

3.1 Ventura Ranch Farmworker Housing Project Evacuation

Evacuation is considered by many to offer the highest level of life protection to the public, but it can also result in evacuees being placed in harm's way if the time available for evacuation is insufficient (Cova et al. 2011). It is estimated that the maximum amount of time needed to move the Ventura Ranch Farmworker Housing Project population to urbanized and/or designated evacuation areas may require up to approximately 2 hours and 10 minutes under varying constraints that may occur during an evacuation. This does not include additional allowances for the time needed to detect and report a fire, for fire response and on-site intelligence, for phone, patrols, and aerial based notifications, and for notifying special needs citizens.

Wolshon and Marchive (2007) simulated traffic flow conditions in a computer derived Wildland Urban Interface (WUI) under a range of evacuation notice lead times and housing densities. To safely evacuate more people, they recommended that emergency managers (1) provide more lead time to evacuees and (2) control traffic levels during evacuations so that fewer vehicles are trying to exit at the same time.

Wildfire emergency response procedures will vary depending on the type of wildfire and the available time in which decision makers (VCFD, VCSO, and/or County Office of Emergency Services) can assess the situation and determine the best course of action. Based on the Project and surrounding communities, its road network, and the related fire environment, the first and primary type of evacuation envisioned is an orderly, pre-planned evacuation process where people are evacuated to more urban areas further from an encroaching wildfire (likely to the SR-33, North Ventura Avenue, or the U.S. Route 101 so evacuees can travel south towards the urban areas of the City of Ventura) well before fire threatens.

The second type of evacuation, which is highly undesirable from a public safety perspective, is an evacuation that occurs when fire ignites close to vulnerable communities. This type of situation is inherently dangerous because there is generally a higher threat to persons who are in a vehicle on a road when fire is burning in the immediate area than in a well-defended, ignition-resistant home. Conditions may become so poor that the vehicle drives off the road or crashes into another vehicle, and flames and heat overcome the occupants. A vehicle offers little shelter from a wildfire if the vehicle is situated near burning vegetation or catches fire itself. This type of evacuation must

be considered a very undesirable situation by law and fire officials in all but the rarest situations where late evacuation may be safer than seeking temporary refuge in a structure (such as when there are no nearby structures, the structure[s] is/are already on fire, or when there is no other form of refuge). Temporary refuge would be possible within the Project's structures, but structures within surrounding communities, as previously discussed, are less desirable due to their higher vulnerability to ignition.

The third potential type of evacuation is a hybrid of the first two. In cases where evacuation is in process and changing conditions result in a situation that is considered unsafe to continue evacuation, it may be advisable to direct evacuees to pre-planned temporary refuge locations, including their own home if it is ignition-resistant and defensible. As with the second type of evacuation discussed above, this situation is considered highly undesirable, but the evacuation pre-planning must consider these potential scenarios and prepare decision makers at the IC level and at the field level for enacting a contingency to evacuation when conditions dictate.

Indications from past fires and related evacuations, in Ventura County and throughout Southern California, which have experienced increasingly more frequent and larger fires, are that evacuations are largely successful, even with a generally unprepared populace. It then stands to reason that an informed and prepared populace would minimize the potential evacuation issues and related risk to levels considered acceptable from a community perspective.

Evacuation orders or notifications are often triggered based on established and pre-determined buffers, which are based on topography, fuel, moisture content of the fuels and wind direction. Evacuations are initiated when a wildfire reaches or crosses one of these pre-determined buffers. Evacuations can also be very fluid. The Incident Command, law enforcement, and OES would jointly enact evacuations based on fire behavior.

3.1.1 Evacuation of Special Populations and Individuals with Access and Functional Needs

Vogt (1990, 1991) defines special populations as those groups of people who, because of their special situations or needs, require different planning strategies from those of the general population. Special needs populations in Solomon Hills include people with access and functional needs (AFN), the hearing or visually impaired, senior citizens, foreign speaking, visitors passing through the area, temporary visitors such as day workers or customers.

People with AFN refers to individuals with physical, intellectual, or developmental disabilities, chronic conditions, injuries, limited English proficiency or who are non-English speaking; older adults; children; people living in institutionalized settings, or those who are low-income, homeless, pregnant or transportation disadvantaged, including, but not limited to, those who are dependent on public transportation or are pregnant (CalOES 2023).

Special populations and temporary visitors may not have knowledge of the area's fire hazard, they may not know how to react in a fire emergency, and they may not understand what they are being told to do. To ensure all members of the community understand the emergency alerts and resources available, Unified Command should use accessible messaging and communication methods. Individuals with AFN may not be able to evacuate themselves in their own vehicles or may be carless. To prepare for emergency transportation to evacuate special populations, the Project should identify their transportation resources that will be available to special populations, and if deemed insignificant, should enter a joint agreement with transportation providers and paratransit agencies in surrounding areas.

Individuals with AFN should create a personal emergency plan for themselves and, if necessary, their service animals.

3.1.2 Animal Evacuations

Animal evacuations present a host of challenges that may affect the overall successful movement of people and their possessions out of harm's way. For example, livestock owners do not always have the means to load and trailer their livestock out of the area. Further, most wildfire evacuation relief shelters or commercial lodging facilities do not allow people to bring in pets or other animals. Sorensen and Vogt (2006) indicate that an issue receiving increasing attention is what evacuees do with pets or other animals such as livestock when they leave their homes and whether having pets or animals impacts their decision to evacuate.

Large animals require additional emergency planning, Ventura County Animal Services provide guidance and support to County residents on preparing and assisting with large animal evacuations. https://animalservices.venturacounty.gov/

This Project does not propose any land uses that would support large animals or livestock onsite.

3.1.3 Re-entry Procedures

An important component of evacuations is the citizen re-entry process. Guidance and procedures to ensure a coordinated, safe, and orderly repopulation into impacted communities following an incident is provided in the County All Hazards Evacuation Plan, Attachment 1: Re-entry/ Repopulation Toolkit.

Ventura County may take a phased approach to re-entry to manage the number of people entering the area of the disaster for public safety purposes.

Incident Commander/Unified Command of the Incident Management Team, with the support of the Director of the Emergency Services Department, the EOC Director, and the Operations Section Chief at the EOC is responsible for coordinating the re-entry procedures with all involved agencies and ensuring effective communication. In the event the EOC has been deactivated, the Incident Commander will initiate re-entry procedures.

Priorities for re-entry include:

- The impacted areas must be thoroughly investigated to ensure it is safe for residents to return and normal operations have been restored. This assessment will verify:
    - The public will be notified of the re-entry status through the notification measures previously mentioned in this WES, including VC ALert, emergency broadcast radio, television, press releases, informational phone-lines such as 2-1-1, community briefings, and informational updates at shelters.
    - Once evacuees are permitted to return, it is important that procedures are established to properly identify residents and critical support personnel, as well as ensure the legitimacy of contractors, insurance adjustors, and other personnel. Re-entry points should be staffed by law enforcement personnel.

3.2 Civilian and Firefighter Evacuation Contingency

As of this document's preparation, no community in California has been directed to shelter-in-place during a wildland fire. Even the communities in Rancho Santa Fe, California, which are designed and touted as shelter-in-place communities, were evacuated during the 2007 Witch Creek Fire. This is not to say that people have not successfully sheltered-in-place during wildfire, where there are numerous examples of people sheltering in their homes, in hardened structures, in community buildings, in swimming pools, and in cleared or ignition-resistant landscape open air areas. The preference will always be early evacuation following the "Ready, Set, Go!" model, but there exists the potential for unforeseen civilian evacuation issues, and having a contingency plan will provide direction in these situations that may result in saved lives.

Potential problems during wildfire evacuation from the Project area include:

- Inadequate time to safely evacuate
- Fire evacuations during rush hour traffic or when large events are occurring
- Blocked traffic due to accidents or fallen tree(s) or power pole(s)
- The need to move individuals who are unable to evacuate

As part of the Project's approval process, detailed plans are required to be submitted to the County and will be provided to VCFD and VCSO to support pre-planning. These pre-planning efforts focus on evacuation contingency planning for civilian populations when it is considered safer to temporary seek a safer refuge than evacuation.

As discussed throughout, the Project's structures would allow for the possibility of temporary sheltering while structures in surrounding communities would not typically be considered ignition-resistant and therefore, not appropriate for temporary refuge.

3.2.1 Safety Zones

The International Fire Service Training Association (IFTSA; Fundamentals of Wildland Fire Fighting, 3rd Edition) defines "safety zones" as areas mostly devoid of fuel, which are large enough to assure that flames and/or dangerous levels of radiant heat will not reach the personnel occupying them. Areas of bare ground, burned over areas, paved areas, and bodies of water can all be used as safety zones. The size of the area needed for a safety zone is determined by fuel types, its location on slopes and its relation to topographic features (chutes and saddles) as well as observed fire behavior. Safety zones should never be located in topographic saddles, chutes or gullies. High winds, steep slopes or heavy fuel loads may increase the area needed for a safety zone.

The National Wildland Fire Coordinating Groups, Glossary of Wildland Fire Terminology provides the following definitions for safety zones:

> *Safety Zone*. An area cleared of flammable materials used for escape in the event the line is outflanked or in case a spot fire causes fuels outside the control line to render the line unsafe. In firing operations, crews progress so as to maintain a safety zone close at hand allowing the fuels inside the control line to be consumed before going ahead. Safety zones may also be constructed as integral parts of fuel breaks; they are greatly enlarged areas, which can be used with relative safety by firefighters and their equipment in the event of blowup in the vicinity.

According to The National Wildland Fire Coordinating Groups, safety zone(s):

- Must be survivable without a fire shelter
- Can include moving back into a clean burn
- May take advantage of natural features (rock areas, water, meadows)
- Can include constructed sites (clear-cuts, roads, helistops)
- Are scouted for size and hazards
- Consider the topographic location (larger if upslope)
- Should be larger if downwind
- Should not include heavy fuels
- May need to be adjusted based on site-specific fire behavior

The definition for a safety zone includes provisions for separation distance between the firefighter and the flames of at least four times the maximum continuous flame height. Distance separation is the radius from the center of the safety zone to the nearest fuels. Due to the dynamic nature of wildfire events it is important to have multiple contingencies, the urbanized areas nearby the Project site (e.g., paved roadways such as SR-33 and the Ventura Freeway Route 101) offer the best possibility for a safety zone for firefighter use. The Project will also include the ability for firefighters to seek safety zones within the ignition-resistant landscapes, but identification of other potential safety zones will require additional focused study by VCFD and other fire and law enforcement agencies.

3.2.2 Temporary Firefighter Refuge Areas

FIRESCOPE California (Firefighting Resources of Southern California Organized for Potential Emergencies) was formed by legislative action to form a partnership between all facets of local, rural, and metropolitan fire departments, CAL FIRE and federal fire agencies. FIRESCOPE defines a contingency plan when it is not possible to retreat to a safety zone. This contingency includes establishment of firefighter temporary refuge areas (TRAs), which are defined as:

> A preplanned area where firefighters can immediately take refuge for temporary shelter and short-term relief without using a fire shelter in the event that emergency egress to an established safety zone is compromised.

Examples of a TRA may include the lee side of a structure, inside of a structure, large lawn or parking areas, or cab of a fire engine, amongst others. Differences between a TRA and a Safety Zone is that TRAs are closer to the immediate firefighting area, are considered a contingency to being able to get to a safety zone, do not include a requirement for a large area set back four times the flame lengths of adjacent fuels, and cannot be feasibly pre-planned until firefighters arrive on-scene and size up the situation.

FIRESCOPE appropriately notes that although safety zones and viable escape routes shall always be identified in the WUI environment, they may not be immediately available should the fire behavior increase unexpectedly. Often a TRA is more accessible in the WUI environment. A TRA will provide temporary shelter and short-term relief from an approaching fire without the use of a fire shelter and allow the responders to develop an alternate plan to safely survive the increase in fire behavior.

The major difference between a TRA and a safety zone is that a TRA requires another planned tactical action (i.e., TRAs cannot be considered the final action, but must include self-defense and a move out of the area when the fire threat subsides). A TRA should be available and identified on site at a defended structure. TRAs are NOT a substitute for a safety zone. TRA pre-planning is difficult, at best because they are very site- and fire behavior-specific. For the Project site, TRAs would likely include navigating into the densely developed areas where firefighters would be separated from the unmaintained wildland fuels by wide areas including site-wide maintained landscapes, ignition-resistant residences, and wide roads that offer numerous opportunities for TRA.

The majority of Project site would be developed and paved surfaces, such as the parking areas, are considered TRAs. This is an important concept because it offers last-resort, temporary refuge of firefighters, and in a worst-case condition, occupants. This approach would be consistent with FIRESCOPE California (2013), which indicates that firefighters must determine if a safe evacuation is appropriate and if not, to identify safe refuge for those who cannot be evacuated, including civilians.

Each of the Project's structures that can be considered for TRA include the following features:

- Ignition-resistant construction materials
- Wide roadways with fire hydrants
- Annual landscape inspections by 3rd party inspectors
- Maintained landscapes and roadside fuel modification
- Ember-resistant vents
    - Interior fire sprinklers

Because there is the possibility that evacuation of the Project and surrounding communities may be less safe than temporarily refuging on site, such as during a fast-moving, wind-driven fire that ignites nearby, including temporary refuge within onsite structures that have been properly designed, constructed, and maintain with fire safety features (e.g., ignition resistant construction, fuel modification) is considered a contingency plan for the Project. This concept is considered a component of the "Ready, Set, Go!" model as it provides a broader level of "readiness" should the ability to execute an early evacuation be negated by fire, road congestion, or other unforeseen issues.

Note: This approach would be considered a last-resort contingency during wildfire with the primary focus being on early evacuation. The decision for evacuation or temporarily refuging onsite will be made by responding law enforcement and/or fire personnel.

3.2.3 Shelter-in-Place

The shelter-in-place strategy, as described above, is the preferred method of protection for people that are not directly impacted, in the direct path of a hazard or it is not safe to evacuate. Shelter-in-place will reduce congestion and transportation demand on the major transportation routes for those that have been directed to evacuate by police or fire personnel. The communities nearby the Project site may include structures in varying states of ignition resistance. If the buildings are older and not built to the current building codes, including Chapter 7A, ignition resistant standards, responding fire and law enforcement personnel may not be able to direct existing occupants to temporarily refuge in their homes. Due to the fire safety features of the proposed development (e.g., Class A

roofs, stucco exterior, interior sprinklers and defensible space), the Project occupants it could safely be directed to shelter in place, if necessary.

3.3 PACE Planning for Evacuation

PACE evacuation planning is based on a military concept focused on mitigating risk by developing a strong primary plan along with three back up plans. If the Primary plan is compromised, the Alternate plan would be triggered. If the Alternate is considered not functional or not safe, the Contingency Plan is implemented. If that plan is not sufficient, then the evacuation reverts to the Emergency plan. The PACE method is an effective tool that can be applied to evacuations to aid in considering alternatives that afford flexibility through redundant contingencies. The plan provides the following:

Primary: This is the overall preferred plan of action to use based on the most likely and most damaging scenario resulting from hazard analysis.

Alternate: The Alternate plan should, when feasible, be as viable as the Primary plan. Alternate plans are needed because unforeseen circumstances arise during emergency evacuations.

> Developing the Alternate plan includes analyzing the most likely problems that could cause the Primary plan to fail and then come up with a plan that fits with the situation that won't be affected by those problems. Whenever possible, come up with a few to several vulnerabilities in the Primary plan and find an alternate that's just as good but covers all those bases.

Contingency: The contingency evacuation plan is the action that will be implemented if you cannot implement either the Primary or the Alternate action due to compromised safety. The contingency isn't always (or isn't usually) as preferred as the others but is a viable option that doesn't rely on the same actions as the Primary and Alternate.

Emergency: This is the action that is implemented if all three of the previous actions fail. In some respects, it is a last resort that is the least preferred option, but is a viable and safe option, nonetheless. The goal is to utilize an Emergency plan that's independent from reliance on the types of actions in the first three options, is a flexible plan, has the highest probability of succeeding, and offers a reliable option with little potential for compromise.

An emergency plan may not be the most convenient or preferred plan and may include components that are uncomfortable to visitors, but it should be as foolproof as possible. Table 1, PACE Evacuation for the Ventura Ranch Farmworker Housing Project, provides the Project approach to contingency planning using the PACE method.

Table 1 PACE Evacuation Plan for the Ventura Ranch Farmworker Housing Project

Primary: Project will evacuate via the primary evacuation route(s) after receiving evacuation notice utilizing the primary evacuation route(s) as directed by law enforcement/emergency managers. Project specific primary evacuation routes may include SR- 33, Ventura Freeway U.S. Route 101, North Ventura Avenue, Crooked Palm Road, and Shells Road.
Alternate: Project will follow evacuation instructions that may include an alternate plan to utilize secondary routes or to relocate to nearby urban areas based on congested traffic conditions. Notifications that this alternate plan is being implemented will be provided via the notification systems or on-site emergency personnel, media and social media.
Contingency: Due to primary and alternate options being compromised or undesirable, the contingency plan of evacuating smaller, highest vulnerability populations will be implemented. For the Project, this includes moving potentially vulnerable populations of the Project site to nearby areas that may serve as Safe Refuge Areas during a wildland fire. The remaining populations will be instructed to remain in place in the Project structures. Depending on the nature of the emergency, the contingency option may not be available or safe.
Emergency: When the wildfire or other emergency dictates that off-site evacuation is not advised by the primary or alternate evacuation routes, and conditions are such that open air exposure would be unhealthy or unsafe, occupants of the Ventura Ranch Farmworker Housing Project will be directed to shelter in place. Sheltering in place is possible due to the construction materials and irrigated landscape that creates a fire hardened development, as well as the fuel modification zones (FMZs). Sheltering in place may also be the preferred option for other emergencies, e.g., active shooter, earthquake. Persons sheltering in place are advised to remain aware of the situation and move out of the building to a designated safe zone if directed to do so or otherwise necessitated.

INTENTIONALLY LEFT BLANK

4 Evacuation Road Network

4.1 CEQA Significance Standards

The CEQA Guidelines establish the significance criteria that apply to an evaluation of a project's potentially significant impacts relative to wildfire related risks. Relevant to this Study and the Project, those criteria include whether a proposed Project would:

- Substantially impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan; or
- Expose people or structures, either directly or indirectly, to a significant risk of loss, injury or death involving wildland fires

Neither CEQA nor the County of Ventura establishes a time-based threshold for evaluating the potential significance of project impacts with respect to the CEQA criteria quoted above. Public safety, not time, is the guiding consideration for evaluating impacts related to emergency evacuation. For purposes of promoting informed decision making, Sections 4.2 and 4.3 below including the results of evacuation time modeling performed under various scenarios with and without the Project as well as an analysis of those results. The following discloses differences in evacuation times for the Project and areas in the vicinity of the Project under certain of the scenarios. However, based the CEQA significance criteria, the modeling and analysis support the determination made in the Addendum that evacuation traffic generated by the Project does not qualify as a significant adverse impact as the Project would not (i) impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan; (ii) expose people or structures, either directly or indirectly, to a significant risk of loss, injury or death involving wildland fires; or (iii) substantially impair an adopted emergency response plan or emergency evacuation plan.

4.2 Wildfire Evacuation

Wildfire poses an evolving threat to lives and property in an increasing number of communities across the United States (FEMA 2012). While wildfires are a natural part of California's landscape, the fire season in California is starting earlier and ending later each year. In 2020 and 2021, California experienced the deadliest and most destructive wildfires in its history. The size and intensity of these wildfires, fueled by drought, an unprecedented buildup of dry vegetation and extreme winds, caused the loss of more than 100 lives, destroyed thousands of homes and exposed millions of urban and rural Californians to unhealthy air. More recently, the Mountain Fire (2024), Palisades Fire (2025), Eaton Fire (2025) and Hurst Fire[1] (2025) have also resulted in significant loss of structure and life due to wildfire fueled by drought, an unprecedented buildup of dry vegetation and extreme winds. Climate change is considered a key driver of this trend. Warmer spring and summer temperatures, reduced snowpack, and earlier spring snowmelt create longer and more intense dry seasons that increase moisture stress on vegetation and make forests more susceptible to severe wildfire. The length of fire season is estimated to have

[1] The Hurst Fire resulted in the evacuation of the existing uses within the study area.

increased by 75 days across the Sierras and seems to correspond with an increase in the extent of forest fires across the state (CAL FIRE, 2020).

These large and increasingly destructive wildfires have forced many Californians living in the WUI to evacuate when an encroaching wildfire threatens their community. The following provides a summary of the Project's wildfire risk.

The historical fire record shows that most vegetation fires occur during normal, onshore weather conditions, and that such fires account for only a proportionally small amount of the land area burned. Wildfires that occur on normal, non-extreme weather days behave in a much less aggressive manner and pose fewer dangers to life and property because they include less aggressive fire behavior and are easier to control. Terrain and fuel are typically the wildfire drivers. During these non-extreme weather days, vegetation is much more difficult to ignite and does not spread fire as rapidly. While there can be on-shore wind conditions that lead to more aggressive fire behavior, generally in these normal weather situations, firefighters have a very high success rate of controlling fires and keeping them under 10 acres.

Conversely, a small number of wildfires that occur during extreme fire weather (Red Flag or Santa Ana conditions) account for most of the land area burned. The data highlights that the most dangerous fire conditions are those related to a fire that moves rapidly due to high winds and low humidity, whereas under normal conditions fires are likely to be controlled with no evacuation or possibly limited extent, focused evacuations.

Project Wildfire Risk

Fire history is an important component of understanding the potential fire risk for the Project. Fire history data provides valuable information regarding fire spread, fire frequency, ignition sources, and vegetation/fuel mosaics across a given landscape. One important use for this information is as a tool for pre-planning. It is advantageous to know which areas may have burned recently and therefore may provide a tactical defense position, what type of fire burned in the vicinity of the Project site, and how a fire may spread.

Fire history data is available through the California Department of Forestry and Fire Protection's (CAL FIRE) Fire and Resource Assessment Program (FRAP) database.

According to available data from the CAL FIRE in the FRAP database, 67 wildfires have burned within a 5-mile radius of the Ventura Ranch Farmworker Housing Project site since the beginning of the historical fire data record. Recorded wildfires within 5 miles of the project site range in size from approximately less than 1 acres up to approximately 281,790 acres (2017 Thomas Fire), however, the average wildland fire size is approximately 6,672 acres. The 2022 Ana Fire is the most recent fire, which burned approximately 1.8 acres. VCFD may have data regarding smaller fires (less than 10 acres) that have occurred on the site that have not been included herein.

In addition to the fire history discussed above, it is important to note the 2017 Thomas Fire is the only recorded wildfire to have burned acreage within the Project site, measuring at approximately .02 acres in the southeastern corner. In total, approximately 90,000 Ventura County residents were impacted by evacuation orders issued during the Thomas Fire. Similarly, the 2019 Hill-Wooslsey Fire resulted in the evacuation of approximately 80,000 Ventura County residents (Ventura County All Hazards Evacuation Plan, 2024). Given the location of the Project in a VHFHSZ, the fire safety features, which are discussed further in the Project's FPP (Dudek 2025), include compliance with ignition resistant construction and defensible space requirements that will provide an additional buffer to the land uses to the west, slowing the rate of spread; therefore, providing a safer evacuation corridor.

Targeted Evacuations

As evidenced by historical mass evacuations in Ventura County and throughout Southern California, even with roadways that are designed to the applicable requirements, it may not be possible, or even the best response, to move large numbers of persons at the same time as part of a mass-evacuation. Instead, informed, phased or targeted evacuations enable more streamlined evacuations where those at highest risk are moved first.

At the time of the preparation of this WES, Ventura County does not have pre-identified evacuation zones. Instead, in the onset of a wildfire or other emergency requiring an evacuation, the incident commander, and emergency managers create evacuation zones that are specific to that event. The purpose of this approach is to allow incident specific factors, such as wind direction and road access, to assist in predicting the portions of the County most at risk and to evacuate those community members first.

In a wildland fire event, the evacuation zones within the Areas A through Area C have multiple evacuation routes available including: SR-33, U.S. Route 101, N Ventura Avenue, Crooked Palm Road, and the proposed EVA. If an evacuation order is issued, evacuees are likely to be directed westward towards major transportation corridors (i.e., SR-33 and/or U.S. Route 101), away from at-risk areas. Available evacuation routes are identified on Figure 4, Evacuation Routes and Study Areas.

Targeted evacuation, which typically targets the scope of the evacuation to only the area in immediate danger and placing a larger area on standby for evacuation, has replaced mass evacuation as the standard protocol for conducting evacuations. This practice allows for better evacuation operations, reduces gridlock, and reserves sufficient travel way for emergency vehicles.

Target evacuations are possible due to technological advancements and improved evacuation strategies that were learned from prior wildfire evacuation events. This improved approach is reflected in EOPs and the experience of the people tasked with coordinating emergency events and is many times more capable of managing evacuations. With the technology in use today (i.e., VC Alert), evacuations are more strategic and surgical than in the past, evacuating smaller areas at highest risk and phasing evacuation traffic so that it flows more evenly and minimizes the surges that may slow an evacuation. Mass evacuation scenarios where large populations are all directed to leave simultaneously, resulting in traffic delays, are thereby avoided, and those populations most at risk safely evacuate.

<u>Fire Department Responsibilities</u>

- Establish command of the Incident
- Conduct a situation assessment and evaluate the need for evacuations
- Establish an Incident Command Post (ICP) with sufficient room for representatives from other assisting agencies and announce its location
- Request Agency Representative from Law Enforcement to respond to the ICP.

<u>Law Enforcement Responsibilities</u>

- Assign supervisor of the rank of Sergeant or above to the Incident Command Post and request a Deputy to locate with Operations Section Chief
- Maintain ingress and egress routes for emergency vehicles
- Establish perimeter control, keeping unauthorized vehicles and pedestrians out of the involved area. Conduct evaluations, if required, at the direction of the Incident Commander
- Establish anti-looting security patrols, when safe to do so, for evacuated areas within the perimeter
- Maintain a Unit log

Joint Fire and Law Enforcement Responsibilities

- Evaluate and determine whether Law Enforcement role will be as an Agency Representative or Unified Incident Commander, depending on the scope of the Incident
- Assign a Law Enforcement supervisor to work closely with the Operations Section Chief or Incident Commander, whomever is determining the areas to be evacuated
- Assess and validate the need for an Evacuation Warning, Evacuation Order, and/or Shelter in Place — Determine the location, potential size, and direction of Incident travel or spread
- Unified Commanders determine potential for Incident spread and request the appropriate resources to complete the evacuation and mitigate the Incident concurrently

When the Incident Command deems certain areas at risk due to fire conditions, an evacuation order is issued. An evacuation order requires the movement of community members out of a defined area due to an immediate threat to life and property from an emergency incident. An evacuation order should be used when there is a potential for or an actual threat to civilian life, within 1 to 2 hours of such determination or when the Incident Command deems it necessary to protect civilians. The purpose of an evacuation warning, in comparison, is to alert community members in a defined area of a potential threat to life and property from an emergency incident. An evacuation warning may be issued when the potential or actual threat to civilian life is more than 2 hours away.

The Department of Homeland Security (2019) provides supporting data for why jurisdictions have moved to the targeted evacuation approach that leverages the power of situational awareness to support decision making. According to their Planning Considerations: Evacuation and Shelter in Place document, they indicate that delineated zones provide benefits to the agencies and community members. Evacuation and shelter-in-place zones promote phased, zone-based evacuation targeted to the most vulnerable areas, which allows jurisdictions to prioritize evacuation orders to the most vulnerable zones first and limit the need to evacuate large areas not under the threat. Zones help:

- Jurisdictions to understand transportation network throughput and capacity, critical transportation and resource needs, estimated evacuation clearance times, and shelter demand.
- Planners to develop planning factors and assumptions to inform goals and objectives.

- Community members to understand protective actions to take during an emergency.
- Shelters to limit traffic congestion and select locations suitable for the evacuated population.

Additionally, targeted evacuation order/warning aims to ensure proper traffic flow and reduce stress at evacuation sites, some people may still choose to evacuate even if they are not facing an immediate threat. These individuals are known as shadow evacuees, and they increase the demand on the roadway network. The number of shadow evacuees varies from incident to incident, depending on their proximity to the actual fire. The evacuation modeling analysis, in all the Scenarios described below, conservatively assumes the evacuation of all populations within the Study Area.

While the amount of time needed to evacuate the Project would vary by the type of incident, the number of evacuation routes utilized, the amount of mobilization time taken by occupants, actual areas at risk, and other factors, the targeted approach would minimize the size of the area being evacuated.

4.3 Evacuation Modeling

An evacuation model analysis was performed by Dudek Traffic Engineers for the Project to determine how long it would take for occupants of the Project and the other land uses in the study area (Figure 4, Evacuation Areas and Evacuation Routes) to evacuate to nearby urban areas and/or freeways in case of a fire emergency. This analysis was performed in accordance with the requirements of the County OA EOP – Annex, All Hazards Evacuation Plan (September 2024) for the calculation of evacuation times.

As a conservative approach, the following analysis assumes the entire study area (Area A through Area C with and without the Project) evacuating at one time, rather than a target or phased evacuation. As previously stated, there are multiple evacuation routes out of this evacuation zone; therefore, to determine impacts to existing land uses, the model considers evacuation traffic from Area A through Area C and the Project site.

4.3.1 Evacuation Modeling Methodology, Assumptions, and Scenarios

The following provides a summary of the methodology, assumptions and scenarios considered in the evacuation time analysis presented herein.

Evacuation Modeling Methodology

The evacuation times presented in this analysis were determined using the traffic simulation software PTV Vissim. Vissim is a multimodal, microsimulation software that allows for the modeling of numerous vehicle compositions, scenarios, and traffic assignment methods. During a simulation, Vissim collects data from each vehicle every 0.1 seconds, capturing data including the vehicle's location, speed, its time spent stopped or queuing, and the time the vehicle enters or leaves the network.

Additionally, Vissim provides a dynamic traffic assignment (DTA) method for vehicle simulation, which allows the model to take into consideration travel choices, traffic flows, and other costs throughout the simulation such that the interaction between the network and demand can vary with time. For example, as congestion increases or decreases, some routes may become more optimal than others. DTA models recognize those changing conditions

to provide more realistic evaluation results compared to traditional static traffic assignment models, where a vehicle's route is set prior to simulation and does not vary with time during the simulation. PTV recommends running 20 or more simulations when using a DTA model such that a sufficient representation of data is available for each evacuation scenario.

To determine evacuation times, all vehicles simulated under each scenario were recorded, including start times from an origin zone, and end times at a destination zone. An evacuating vehicle is removed from the traffic network, and its time stamp recorded once it passes through a destination zone, which are modeled south on the SR-33 freeway and south on Ventura Avenue to represent safe areas from the evacuation. It is assumed once a vehicle either merges onto SR-33 at the Canada Larga Road or Shell Road interchanges, or reaches Dakota Drive along Ventura Avenue traveling south towards the City of Ventura, it is within a safe area. Evacuation time results are averaged in this report to provide a representative analysis of simulations. A summary of the simulation runs is provided in Attachment C.

Evacuation Modeling Scenarios

The following analysis scenarios are included in this study. All scenarios assume a mass evacuation event in which all vehicles leave the study are simultaneously. Background traffic is not considered in this analysis, populations outside of the study area are not assumed to be included in the same evacuation order as the proposed project and would not be assumed to add vehicles to the roadway network during the evacuation event.

Scenario 1 – Existing Conditions

Existing conditions are representative of current conditions, including roadway and intersection geometrics as well as the number of occupied dwelling units in the study area.

Scenario 2 – Ventura Ranch Farmworker Housing (Project) Only

The isolated Project conditions provide an analysis of evacuation times of Project vehicles only, assumed to be the maximum number of parking spaces available on-site (565 vehicles).

Scenario 3 – Existing plus Project Conditions

The Existing plus Project scenario includes all assumptions from the Existing baseline conditions, with the addition of evacuating vehicles from the proposed Project.

While one cumulative project has been identified in Casitas Springs, located approximately 2.5-3 miles north of the Project site, this project is located outside of the study area. As such, an existing plus cumulative project scenario with and without the Ventura Ranch Farmworker Housing Project has not been included in this study.

Evacuation Routes

The Project would construct two new driveways to Ventura Avenue as well as connect an internal road to the existing residential neighborhood adjacent to the Project's northern boundary, as described further below. No additional external roadways would be constructed with development of the proposed Project. A summary of all evacuation routes assumed in this analysis is also provided below in Figure 4

For the purposes of this analysis, contraflow lanes (e.g., lanes normally meant for westbound traffic would not be redirected to accommodate eastbound traffic) are not assumed along any roadway under the modeled scenarios evaluated in this report.

Additionally, as the study area is located approximately 0.5 miles from SR-33, Travel times from the study area zones under uncongested conditions were validated using Google Maps travel time estimates.

Major Transportation Corridor

State Route 33 (SR-33) serves as the major transportation corridor throughout the region. Within the study area, SR-33r is a 4-lane, divided freeway, providing access to the north into the community of Casita Springs as well as State Route 150. To the south, SR-33 provides access to the City of Ventura and US 101. For the purposes of the analysis, it is assumed that a vehicle will be considered in a safe area once it merges onto SR-33.

Primary Evacuation Routes

Ventura Avenue and Crooked Palm Road will serve as the primary evacuation routes out of the study area. The main Project driveways to Ventura Avenue will serve as the primary evacuation routes for the Project's residential land uses. Ventura Avenue provides access to Canada Larga Road and Shell Road West which allows entry to SR-33.

Ventura Avenue is currently striped as a 2-lane road, extending from US 101 to SR-33. According to Ventura County's General Plan, Ventura Avenue is classified as a Minor Arterial/Major Collector. Upon development of the Project, Ventura Avenue would provide primary access to the Project and serve as access to the water supply. For the purposes of the analysis, it is assumed that a vehicle will be considered in a safe area once it proceeds through the Ventura Avenue and Dakota Drive intersection.

Crooked Palm Road is currently striped as a 2-lane road, extending from Ventura Avenue to the north and reconnecting to Ventura Avenue to the south. Crooked Palm Road does not have a specific roadway classification per the County's General Plan.

Canada Larga Road is currently striped as a 2-lane road, extending from Sulphur Canyon Road to Ventura River Trail. Canada Larga Road does not have a specific roadway classification per the County's General Plan.

Shell Road West is currently striped as a 2-lane road, extending from Ventura Avenue to Mill Canyon Road. Shell Road West does not have a specific roadway classification per the County's General Plan.

Ventura Ranch WES

INTENTIONALLY LEFT BLANK

Evacuation Population

As the Project proposes a residential development, this analysis assumes a night-time evacuation event when the majority of residents of both the Project and surrounding communities are assumed to be in their residences.[2] Population projections and number of vehicles are estimated in Table 2, Project and Surrounding Communities Population Projections and Vehicle Ownership, to both provide a conservative assessment of evacuating populations while also avoiding double-counting of evacuating populations where feasible.

Table 2: Project and Surrounding Communities Population Projections and Vehicle Ownership

Vissim Zone	Name	Land Use	Size[1]	Unit	Average Vehicle Ownership[2]	Total Evacuating Vehicles
A	Ventura Ranch Farmworker Housing Project	Residential	565	Spaces	1.00	565
					Proposed Project (Zone A) Total	**565**
B	Norway Drive	Residential	208	DU	1.97	409
C	Los Cabos-Magnolia	Residential	349	DU	1.97	686
					Surrounding Evacuating Zones B – C (Existing) Total	**1,095**
					Total Zones A – C (Existing plus Project Total)	***1,660***

Notes:

[1] Sizes of the existing surrounding land uses were determined from aerial observations using Google Earth, along with the most recent available data from Parcel Quest and the U.S. Census Bureau in addition to manual counts in areas that did not have dwelling unit data available.

[2] Average Vehicle Ownership Assumptions:

- All land uses are residential (w/"DU" [dwelling unit] as unit) and use a 1.97 vehicles/unit rate to determine number of evacuating vehicles per average vehicles/household rate from Ventura County and Census Tract ACS data (2023).

[3] A night-time evacuation event in this study roughly refers to the hours between midnight and 6am, which assumes the time-period during which the highest number of residents are at home and is representative of the land use with the highest number and concentration of evacuating vehicles in the study area. During this time-period, schools, retail, restaurant, and other commercial or service-type land uses are assumed to generate a negligeable number of evacuating vehicles.

4.3.2 Modeling Results

Based on the analysis methodology described in the previous section, Table 3, Evacuation Modeling Scenarios and Evacuation Time Summary, summarizes the evacuation time for each analysis scenario. The evacuation time does not depict the evacuation time for each individual person within an evacuation area, but rather the total amount of time needed to evacuate all populations modeled from an area. Populations located in closer proximity to the IC designated safe zone will safely evacuate sooner than the total calculated evacuation time identified in Table 3. Detailed evacuation travel time analysis information is provided in Appendix A, Evacuation Modeling Technical Memorandum.

As shown below, in Table 3, the following is a summary of the evacuation time for each scenario:

- Scenario 1: It would take approximately 43 minutes to evacuate the existing land uses.
- Scenario 2: It would take approximately 37 minutes to evacuate the proposed Project.
- Scenario 3: It would take approximately 58 minutes to evacuate the existing land uses and cumulative projects.

Table 3. Evacuation Modeling Scenarios and Evacuation Time Summary

Scenario	Total Evacuation Vehicles			Evacuation Time (Minutes) by Area		Maximum Evacuation Time by Scenario (H:MM)	Average Evacuation Time by Scenario (H:MM)
	Existing Areas	Ventura Ranch Farmworker Housing Project Area	Total	Existing Areas	Ventura Ranch Farmworker Housing Project Area		
1: Existing 2025	1,095	0	1,095	43.91	0.00	**0:43**	**0:40**
2: Project Only	0	565	565	0.00	37.98	**0:37**	**0:37**
3: Existing plus Project	1,095	565	1,660	53.53	58.55	**0:58**	**0:53**

Notes: 00.00 = Maximum evacuation time for each scenario (time for last vehicle to leave the network and enter a safe area)

In Scenario 1, Existing 2025, the evacuation of 1,095 vehicles from the study area to merge onto the SR-33 resulted in an evacuation time of approximately 43 minutes. In Scenario 2, Project Only, the evacuation of 565 vehicles from the Project site, merging onto the SR-33, resulted in an evacuation time of approximately 37 minutes . In Scenario 3, Existing plus Project, the evacuation of 1,660 vehicles from the study area to merge onto the SR-33 resulted in an evacuation time of approximately 58 minutes. The difference in average evacuation times when comparing the existing 2025 conditions to the existing plus Project conditions resulted in an increase of 13 minutes, with a maximum evacuation time increase of 15 minutes.

4.4 Potential for Project Evacuation Impacts

There are currently no significant standards for evacuation travel time for the Project area or established in the CEQA Guidelines. Public safety, not time, is generally the guiding consideration for evaluating impacts related to emergency evacuation. The County considers a Project's impact on evacuation significant if the Project would significantly impair or physically interfere with implementation of an adopted emergency response or evacuation plan; or if the Project would expose people or structures to a significant risk of loss, injury, or death involving wildland fires.

Safely undertaking large-scale evacuations may take several hours or more and require moving people long distances to designated areas. Further, evacuations are fluid and timeframes may vary widely depending on numerous factors, including, among other things, the number of vehicles evacuating, the road capacity to accommodate those vehicles, occupants' awareness and preparedness, evacuation messaging and direction, and on-site law enforcement control.

Notwithstanding evacuation challenges and variables, the success rate in the County in safely managing both mass and targeted evacuations is very high. For example, the 2017 Thomas Fire caused 31 evacuation orders to more than 90,000 residents, with CAL FIRE and VCFD reporting 1 civilian and 1 firefighter fatality (Ventura County All Hazards Evacuation Plan, 2024). Losses of life in virtually every large wildfire were related to persons who ignored initial evacuation warnings, many of whom were located in rural areas with long, exposed evacuation routes. Technological advancements and improved evacuation strategies learned from prior wildfire evacuation events have resulted in a system that is many times more capable of managing evacuations. With the technology in use today in the County, evacuations are more strategic and surgical than in the past, evacuating smaller areas at highest risk and phasing evacuation traffic so that it flows more evenly and minimizes the surges that may slow an evacuation. Mass evacuation scenarios where large populations are all directed to leave simultaneously, resulting in traffic delays, are thereby avoided, and those populations most at risk safely evacuate. As implemented in past wildfire evacuations, an early evacuation of the area may occur several or more hours prior to actual threatening conditions at the Ventura Ranch Farmworker Housing Project site, depending on conditions and fire spread projections.

In an evacuation, the Project occupants would primarily utilize SR-33 and U.S. Route 101, as illustrated in Figure 4 – Evacuation Routes. Based on the typical road capacity, an evacuation of the Project site and surrounding land uses, under worst-case conditions, would take approximately 59 minutes to evacuate if all traffic was using the SR-33. While one cumulative project has been identified in Casitas Springs, located approximately 2.5-3 miles north of the Project site, this project is located outside of the study area. As such, an existing plus cumulative project scenario with and without the Ventura Ranch Farmworker Housing Project has not been included in this study. Cumulative impacts would be limited to ambient growth, which would not contribute enough evacuation traffic to result in a significant impact on evacuation.

As discussed above, the Project would provide emergency managers the alternative option of recommending occupants to temporarily seek refuge on site in fire-resistant buildings or within the converted landscapes and hardscapes that would not readily facilitate wildfire spread. This would provide emergency managers with a safer alternative to risking a late evacuation. Additionally, the Project would provide a new north/south evacuation route that would provide secondary access for the Project as well as the community to the north. Further, the Project does not propose to cut off or otherwise modify existing evacuation routes. Considering these facts and others presented herein, the Project would not expose people to a significant risk of loss or death involving wildland fires related to evacuation, would not interfere with evacuation response planning, and would not result in inadequate emergency access.

4.4.1 Efficacy of Modern Code Conversation

The Project's proposed residential development includes safe corridors, ingress and egress points, and available evacuation routes. The perimeter FMZs would keep an active flaming front at great distances from structures and support defensibility for the existing fire environment. These features make the Project substantially more resilient to potential fire hazards than developments where vegetation is allowed to grow between and among structures. Alexandra D. Syphard, a fire expert who has studied fire conditions in San Diego County, has consistently maintained that low to medium density developments that are interspersed or inter-mixed with wildland vegetation have the highest risk of fire-related damage (Syphard, et. al. 2013, Syphard et. al. 2017. Syphard, et. al. 2020). Although her research occurred in San Diego County, the general topography and vegetation that was present in the study areas are similar to those found across Southern California, including the project location, in Ventura County.

Ms. Syphard's long-held position that higher-density developments built with ignition-resistant building materials and defensible space requirements, which has been specified for the proposed Project in the FPP, fare much better because defensible space reduces the flame length and spread of fire and ignition resistant construction limits ember intrusion and increases the time it takes for a structure to catch fire. These measures also significantly improve the ability of structures (and people) to survive wildfires.

Similar to these examples, the Ventura Ranch Farmworker Housing Project includes a multi-layered fire protection system that is based on ignition resistant buildings and landscapes, adherence to stringent codes, fire-fighting water availability, and sound evacuation planning that includes a contingency option for residents who may be directed to temporarily shelter within the community during a wildfire evacuation. The Project, like other new, master-planned communities, should not be compared with older, less restrictive communities that were not built in compliance with the latest building and fire codes or conducting ongoing maintenance for fuel modification. Other new communities, such as those in the Castaic community during the 2025 Hughes Fire, have performed extremely well during wildfires; given the Project's location, surrounding fire environment, and proposed fire protection plans, it is anticipated that the Project will represent lowered risk to both Project residents and nearby neighboring communities.

INTENTIONALLY LEFT BLANK

5 Wildfire/Evacuation Awareness

Although not required by regulation or code, nor relied upon for purposes of reaching the significance conclusions set forth in this WES, the Project can be proactive in its outreach to its occupants regarding fire safety, wildfire and evacuation awareness, and general evacuation procedures. Educating populations in FHSZ and WUI areas on wildfire safety and evacuation can make for an even more efficient and effective evacuation, such as understanding how to receive emergency notifications and the different types of notifications keeps occupants informed, what to include in your emergency kit for your home or vehicle keeps occupants ready to evacuate when notified, encouraging evacuees to carpool helps reduce the number of vehicles on evacuation roadways. Similarly, the Project can also coordinate with local fire agencies to engage occupants in fire safety and evacuation awareness through a variety of methods as described further below.

The focus of the "Ready, Set, Go!" program is on public awareness and preparedness, especially for those living and working in the WUI areas. The program is designed to incorporate the local fire protection agency as part of the training and education process in order to ensure that evacuation preparedness information is disseminated to those subject to the potential impact from a wildfire. There are three components to the program:

- "READY" – Preparing for the Fire Threat**:** Take personal responsibility and prepare long before the threat of a wildfire so you are ready when a wildfire occurs. Confirm you are registered for Wireless Evacuation Alerts, and VC Alert. Make sure all occupants have an individual Action Plan.
- "SET" – Situational Awareness When a Fire Starts: If a wildfire occurs and there is potential for it to threaten the Ventura Ranch Farmworker Housing Project and surrounding communities, pack your vehicle with your emergency items. Stay aware of the latest news from local media and your local fire department for updated information on the fire. If you are uncomfortable, leave the area.
- "GO!" – Leave Early! Following your Action Plan provides you with knowledge of the situation and how you will approach evacuation. Leaving early, well before a wildfire is threatening the area, provides you with the least delay and results in a situation where, if a majority of neighbors also leave early, firefighters are now able to better maneuver, protect and defend structures, evacuate other occupants who couldn't leave early, and focus on citizen safety.

"READY SET GO!" is predicated on the fact that being unprepared and attempting to flee an impending fire late (such as when the fire is physically close to your community) is dangerous and exacerbates an already confusing situation. This Ventura Ranch Farmworker Housing Project WES provides key information that can be integrated into the individual Action Plans, including the best available routes to use in the event of an emergency evacuation.

Situation awareness requires a reliable information source. One of the most effective public notification methods is Reverse 911. The Ventura County Sheriff OES operates the Reverse 911 notification system that provides a recorded message over land line telephone systems relating to evacuation notices. In addition, OES operates a program known as VC Alert that has the capability to send emergency notifications over both land lines as well as to cell phones and via text messages. It is up to individual employees to register their cell phones for VC Alert. The registration of cell phones can be done online at https://www.readyventuracounty.org/vc-alert/. In addition, the Ventura County Emergency Alert System is county-wide and broadcasts emergency information via three radio stations: KVTA 1590 AM, KHAY 100.7 FM, KNLA 103.7 FM (Spanish).

The following provides examples of best practices for how the Project could proactively implement a wildfire and evacuation awareness program. Appendix B, Federal Preparedness Resources, and Appendix C, State and Local Preparedness Resources, offer preparedness resources that can be used for outreach.

Ventura Ranch Farmworker Housing Project can identify a Fire Safety Coordinator that is responsible for:

1. Overseeing implementation of this WES and overall fire coordination with VCFD and VCSO.

2. Implementing a proactive facility wildfire education program utilizing a multi-pronged approach to fire safety following the "**Ready, Set, Go!"** approach to wildfire evacuation, to include, but not limited to:

    i. Annual wildfire and evacuation safety awareness meeting in coordination with local fire agencies.
    ii. Annual reminder notices will be provided to each employee encouraging them to review this WES and be familiar with evacuation protocols.
    iii. The Project website will host a webpage dedicated to wildfire and evacuation education and awareness, which should include a copy of this Wildfire Evacuation Study and the resources provided herein.

3. Coordinating an annual fire evacuation drill/ fire exercise to ensure proper safety measures have been implemented, facility awareness and preparation of a facility-wide **Ready, Set, Go!"** plan.

4. Organizing an employee training and awareness through various practices:

    i. New hire fire awareness and evacuation training
    ii. Ongoing staff training
    iii. Facility sweeps by trained staff
    iv. Strategically placed fire safety and evacuation/sheltering protocol information, as determined by the Fire Safety Coordinator.

While the practices above for would support an informed populace and would further improve safety and reduce and/or avoid problems during an evacuation, the evacuation modeling herein is not predicated on implementation of those practices. Therefore, as previously demonstrated, the Project would not expose people or structures to a significant risk of loss, injury or death involving wildland fires or substantially impair implementation of or physically interfere with an adopted emergency evacuation plan or emergency response plan.

INTENTIONALLY LEFT BLANK

6 Limitations

Wildfire Evacuation Study ("WES")

This WES analyzes the existing community's evacuation times currently, and assuming the construction of the Project as it relates to wildfires; however, the components of the plan may also be useful in similar situations, as noted above. The estimated evacuation times are based on several assumptions detailed in this WES. However, actual evacuation times may be faster or slower than the estimates, depending on the type of emergency, the extent of the evacuation, its gravity, the time of day, and other factors. A collective, community–wide evacuation of existing populations and the proposed population from the Project would include congested roads in its existing condition that are improved, but still congested with the Project. Congested roads are normal in any urban setting when a large evacuation is declared unless it is managed appropriately (*e.g.*, evacuation areas are staggered to reduce the potential traffic surges that can significantly impact evacuations), there would still be the potential for congestion and delays.

This WES promotes the "Ready, Set, Go!" model, adopted by Ventura County Fire Department, CAL FIRE, and many fire agencies statewide. The goal is to raise agency and citizen awareness of potential evacuation issues and get a majority of the public "Ready" by taking a proactive stance on preparedness, training drills, and resident education, and evacuation planning efforts.

The Project populace will be "Set" by closely monitoring the situation whenever fire weather occurs and/or when wildfire occurs and elevating pre-planned protocol activities and situational awareness.

Lastly, fire or law enforcement officials will mandate that populations "Go" by executing pre-planned evacuation procedures. The preferred alternative, initially, may well be early evacuation. However, there may be instances when evacuation is not possible, is not considered safe, or is not an option based on changing conditions, or other factors.

The Project also is designed specifically to maintain an enhanced resistance to wildfire ignition and perform as a fire adapted Project, offering fire and law officials with additional options for safety to the populace compared to those options available to less thought-through projects.

As noted, this WES does not and cannot provide any guarantees. Fire is a dynamic and unpredictable occurrence, and it is important for those in a high fire severity zone to educate themselves on practices that will improve safety and that will be able to be implemented at the individual level rapidly and effectively, albeit in combination with protocols and "in-the-field" decision making of emergency responders.

Summary – Vehicle Travel Time Scenarios

This WES presents a reasonable vehicle travel time estimate based on professional judgments made by Dudek, taking into consideration input from Dudek and other resources. Changing any number of these assumptions can lengthen or shorten the average vehicle travel time. For instance, a situation could arise in which professionals *may* choose to utilize additional roadways for evacuation not utilized in the Dudek analysis and *may also* choose to send more vehicle trips to certain evacuation routes and *may also* choose to guide vehicle trips to more or different route permutations relative to what has been modeled in this the Dudek analysis. The net result of changing the variables selected could yield an average evacuation travel time shorter or longer than the results detailed in the Dudek analysis.

Many factors can shorten or lengthen the vehicle time from the results shown herein. For example:

1. Changing the possible evacuation routes selected would affect the results. For instance, utilizing roads for ingress and/or egress that are not utilized in this analysis could shorten vehicle travel times relative to the results shown herein.
2. Increasing or decreasing the number of path permutations and percentage of the population utilizing each route that leads out of the immediate area could shorten or lengthen vehicle travel time relative to the results shown herein.
3. Emergency professionals electing to reserve certain road lanes for emergency vehicle ingress for portions of time could affect the travel time relative to the results shown herein.
4. Assuming evacuees utilize fewer or more vehicles to evacuate from the Project or surrounding communities relative to the Vehicle Utilization Rate selected in the analysis would shorten or lengthen vehicle travel time relative to the results shown herein.
5. Changing the mix of vehicle trips allocated to each evacuation route could shorten or lengthen vehicle travel time relative to the results shown herein.
6. Assuming a different road capacity adjustment factor could shorten or lengthen the vehicle travel time relative to the results shown herein.
7. Assuming fewer people are at home when the evacuation notice is given would reduce the number of vehicle trips and shorten vehicle travel time relative to the results shown herein. For instance, an evacuation during daytime hours would typically result in fewer outbound trips than assumed in this analysis.
8. Assuming some portion of vehicle trips are made in advance of the evacuation notice would reduce the number of vehicle trips relative to the results shown herein.
9. Assuming some homeowners and their families are not in the Study Area when evacuation notice is given (most likely in a daytime evacuation event), could reduce the number for vehicle trips relative to the results shown herein.

The evacuation time analysis is necessarily limited in scope given the numerous variables inherent in a wildfire and evacuation event. However, as discussed above, it is not anticipated that the Project will significantly impact evacuation of the proposed or existing surrounding communities based on evacuation times and other qualitative considerations.

Limitation On Reliance Or Dependence Upon Report

Any person or entity furnished with this report and/or who reviews it agrees that the advance written consent of Dudek be sought and furnished to such person or entity prior to the review, reliance or authorization as to any matters that are the subject of the reports by any person or entity (whether through act or omission as set forth in the report), other than Dudek's direct client. In such case, obtaining Dudek's consent shall not be subject to any fee or charge (other than reasonable copy costs, where applicable).

Dudek expressly disavows, does not assume any responsibility for, nor will be liable for any claims, losses, or damages associated with any matters that are the subject of this or other reports it prepares or contributes to respecting this project, however characterized (including without limitation as sounding in tort, breach of contract, misrepresentation by act or omission, failure to adhere to applicable standards of professionalism, statutory liability, etc.), whether in law or equity, whether known or unknown, and whether actual or contingent, excepting only Dudek's direct client, as to which the limitation of liability provisions in the contract between Dudek and its client shall govern.

	Mike Huff, Dudek
Attachment(s):	Figures 1-3
	Attachment A – Vehicle Ownership Census Data
	Attachment B – Evacuating Population Tables for all Scenarios
	Attachment C – Vissim Evacuation Analysis Worksheets
	Attachment D – Evacuation Analysis Summary Charts and Tables

This technical memorandum provides an emergency evacuation modeling analysis of vehicles from the proposed Ventura Ranch Farmworker Housing Project (Project), and provides an assessment of the time required to evacuate the Project Area under three (3) scenarios during a wind-driven fire event requiring evacuation of the Project and the surrounding communities.[1] This memorandum serves as a technical resource to provide evacuation times simulated during various evacuation scenarios, and should not be used in place of, or solely as, an Evacuation Plan.

1 Project Description

The overall Ventura Ranch development is comprised of approximately 82.92 acres of land. The Ventura Ranch Project Site is in the unincorporated Ventura County, north of the City of Ventura. The Project is in Ventura's sphere of influence but not immediately adjacent to a city boundary. The Project is directly south of the Valley Vista community (Figure 1, Project Location). Access to Project is provided by two access points on Ventura Avenue. Immediately adjacent to the Project Site is a combination of residential, agricultural, and open space land uses. To the north, the Project Site is bordered by a residential community; to the west, the Site is bordered by open land; to the south, the Site is bordered by existing residential and commercial uses; and to the east, the sites are bordered by a combination of industrial, agricultural, and open spaces.

The Ventura Ranch Project (Project) is a proposed residential community on vacant land located near the agricultural regions of the Oxnard Plain. The Project proposes to provide critical farmworker housing for Ventura County. Ventura Ranch will provide affordable dwelling units exclusively for farmworkers and their families. The project proposes construction of 328 apartments and 565 parking spaces, as well as community spaces such as

[1] This technical memorandum was prepared in coordination with the Ventura Ranch Farmworker Housing Project Wildfire Evacuation Study, prepared by the Dudek Fire Protection and Evacuation Planning Team.

a basketball court, a garden, walking paths, and playgrounds (Figure 2, Site Plan). The apartments range in size from approximately 570 square feet to approximately 1,095 square feet.

Evacuating vehicles from the Project site are included in this modeling analysis and are identified as the Ventura Ranch Farmworker Housing Project Total Scenario. Further discussion of the assumed vehicles included in this analysis and all other modeled assumptions are detailed in Chapter 2 below.

2 Assumptions

Due to the highly variable nature of any type of evacuation event, numerous assumptions must be made when creating evacuation models used to assess traffic impacts. Some of these assumptions include, but are not limited to: the determination of the population that needs to be evacuated, number and type of vehicles used by the evacuating population, operation and control of intersections, number of available egress lanes, routes available at the time of the event, mobilization time and route choice of all populations, exact location of the fire's start and spread, weather conditions, visibility, topography, etc.

Creating models that account for all permutations of these variables would be extremely resource intensive. As such, this technical memorandum provides a representative model of a fire evacuation event under various project scenarios and reports the evacuation times associated with the assumptions below. Assumptions included in this analysis are considered based on a balance of both conservative and realistic assumptions, evaluating all available population and location characteristics available and using of the best available modeling software and methodologies.

During an actual large-scale evacuation event, coordination between many departments, agencies, and organizations under uniform command would be required, and would take into consideration all available information to tailor the evacuation response to the given situation. Evacuation instructions, or directives to shelter-in-place, would be issued by protocols outlined in the Ventura County Operational Area (OA) Emergency Operations Plan (EOP).[2] As such, the traffic model developed for and used in this analysis is meant only to serve as a resource to inform evacuation timeframes, which may be used by agencies and planning authorities in outlining emergency response guidelines.

2.1 Analysis Scenarios

The following analysis scenarios are included in this study. All scenarios assume a mass evacuation event in which all vehicles leave the study are simultaneously. Background traffic is not considered in this analysis, populations outside of the study area are not assumed to be included in the same evacuation order as the proposed project and would not be assumed to add vehicles to the roadway network during the evacuation event.

Scenario 1 – Existing Conditions

Existing conditions are representative of current conditions, including roadway and intersection geometrics as well as the number of occupied dwelling units in the study area.

[2] Ventura County Operational Area Emergency Operations Plan (2021). https://s29710.pcdn.co/wp-content/uploads/2021/03/EOP-Draft-Public.pdf

Scenario 2 – Ventura Ranch Farmworker Housing (Project) Only

The isolated Project conditions provide an analysis of evacuation times of Project vehicles only, assumed to be the maximum number of parking spaces available on-site (565 vehicles).

Scenario 3 – Existing plus Project Conditions

The Existing plus Project scenario includes all assumptions from the Existing baseline conditions, with the addition of evacuating vehicles from the proposed Project.

While one cumulative project has been identified in Casitas Springs, located approximately 2.5-3 miles north of the Project site, this project is located outside of the study area. As such, an existing plus cumulative project scenario with and without the Ventura Ranch Farmworker Housing Project has not been included in this study.

2.2 Circulation Network and Evacuation Routes

The Project would construct two new driveways to Ventura Avenue as well as connect an internal road to the existing residential neighborhood adjacent to the Project's northern boundary, as described further below. No additional external roadways would be constructed with development of the proposed Project. A summary of all evacuation routes assumed in this analysis is also provided below in Figure 3.

For the purposes of this analysis, contraflow lanes (e.g., lanes normally meant for westbound traffic would not be redirected to accommodate eastbound traffic) are not assumed along any roadway under the modeled scenarios evaluated in this report.

Additionally, as the study area is located approximately 0.5 miles from SR-33, Travel times from the study area zones under uncongested conditions were validated using Google Maps travel time estimates.

Major Transportation Corridor

State Route 33 (SR-33) serves as the major transportation corridor throughout the region. Within the study area, SR-33r is a 4-lane, divided freeway, providing access to the north into the community of Casita Springs as well as State Route 150. To the south, SR-33 provides access to the City of Ventura and US 101. For the purposes of the analysis, it is assumed that a vehicle will be considered in a safe area once it merges onto SR-33.

Primary Evacuation Routes

Ventura Avenue and Crooked Palm Road will serve as the primary evacuation routes out of the study area. The main Project driveways to Ventura Avenue will serve as the primary evacuation routes for the Project's residential land uses. Ventura Avenue provides access to Canada Larga Road and Shell Road West which allows entry to SR-33.

Ventura Avenue is currently striped as a 2-lane road, extending from US 101 to SR-33. According to Ventura County's General Plan, Ventura Avenue is classified as a Minor Arterial/Major Collector. Upon development of the Project, Ventura Avenue would provide primary access to the Project and serve as access to the water supply. For the purposes of the analysis, it is assumed that a vehicle will be considered in a safe area once it proceeds through the Ventura Avenue and Dakota Drive intersection.

Crooked Palm Road is currently striped as a 2-lane road, extending from Ventura Avenue to the north and reconnecting to Ventura Avenue to the south. Crooked Palm Road does not have a specific roadway classification per the County's General Plan.

Canada Larga Road is currently striped as a 2-lane road, extending from Sulphur Canyon Road to Ventura River Trail. Canada Larga Road does not have a specific roadway classification per the County's General Plan.

Shell Road West is currently striped as a 2-lane road, extending from Ventura Avenue to Mill Canyon Road. Shell Road West does not have a specific roadway classification per the County's General Plan.

2.3 Evacuating Population

As the proposed Project is a residential development, this analysis assumes a night-time evacuation event when the majority of residents of both the Project and surrounding communities are assumed to be in their residences.[3] Population projections and estimated number of vehicles are estimated in Table 1 to both provide a conservative assessment of evacuating populations while also avoiding double-counting of evacuating populations where feasible. Figure 3 includes the locations and surrounding existing and future developments included in this analysis.

[3] A night-time evacuation event in this study roughly refers to the hours between midnight and 6am, which assumes the time-period during which the highest number of residents are at home and is representative of the land use with the highest number and concentration of evacuating vehicles in the study area. During this time-period, schools, retail, restaurant, and other commercial or service-type land uses are assumed to generate a negligeable number of evacuating vehicles.

Table 1. Project and Surrounding Communities Population Projections and Vehicle Ownership

Vissim Zone	Name	Land Use	Size[1]	Unit	Average Vehicle Ownership[2]	Total Evacuating Vehicles
A	Ventura Ranch Farmworker Housing Project	Residential	565	Spaces	1.00	565
					Proposed Project (Zone A) Total	**565**
B	Norway Drive	Residential	208	DU	1.97	409
C	Los Cabos-Magnolia	Residential	349	DU	1.97	686
					Surrounding Evacuating Zones B – C (Existing) Total	**1,095**
					Total Zones A – C (Existing plus Project Total)	***1,660***

Notes:

[1] Sizes of the existing surrounding land uses were determined from aerial observations using Google Earth, along with the most recent available data from Parcel Quest and the U.S. Census Bureau in addition to manual counts in areas that did not have dwelling unit data available.

[2] Average Vehicle Ownership Assumptions:

- Surrounding residential (w/"DU" [dwelling unit] as unit) and use a 1.97 vehicles/unit rate to determine number of evacuating vehicles per average vehicles/household rate from Ventura County and Census Tract ACS data (2023). See Attachment A.
- Ventura Ranch Farmworker Housing (Project) utilizes total provided parking as tabulated in the Project Site Plan (see Figure 2) to determine number of evacuating vehicles.

3 Methodology

The evacuation times presented in this analysis were determined using the traffic simulation software PTV Vissim. Vissim is a multimodal, microsimulation software that allows for the modeling of numerous vehicle compositions, scenarios, and traffic assignment methods. During a simulation, Vissim collects data from each vehicle every 0.1 seconds, capturing data including the vehicle's location, speed, its time spent stopped or queuing, and the time the vehicle enters or leaves the network.

Additionally, Vissim provides a dynamic traffic assignment (DTA) method for vehicle simulation, which allows the model to take into consideration travel choices, traffic flows, and other costs throughout the simulation such that the interaction between the network and demand can vary with time. For example, as congestion increases or decreases, some routes may become more optimal than others. DTA models recognize those changing conditions to provide more realistic evaluation results compared to traditional static traffic assignment models, where a vehicle's route is set prior to simulation and does not vary with time during the simulation. PTV recommends running 20 or more simulations when using a DTA model such that a sufficient representation of data is available for each evacuation scenario.

To determine evacuation times, all vehicles simulated under each scenario were recorded, including start times from an origin zone, and end times at a destination zone. An evacuating vehicle is removed from the traffic network, and its time stamp recorded once it passes through a destination zone, which are modeled south on the SR-33 freeway and south on Ventura Avenue to represent safe areas from the evacuation. It is assumed once a vehicle either merges onto SR-33 at the Canada Larga Road or Shell Road interchanges, or reaches Dakota Drive along Ventura Avenue traveling south towards the City of Ventura, it is within a safe area. Evacuation time results are averaged in this report to provide a representative analysis of simulations. A summary of the simulation runs is provided in Attachment C.

4 Evacuation Analysis

To evaluate the evacuating vehicles from the Project and surrounding existing and planned communities, the Vissim network is modeled with origin zones, as identified in Table 1 above. Using a conservative approach, the worst-case scenario was assumed, in which all vehicles belonging to households in the study area, instead of the necessary number of vehicles needed to evacuate the impacted population. Table 3 summarizes the evacuation times by area type. The highest evacuation time shown in Table 3 is also the maximum evacuation time, or the time it takes for the last vehicle to leave the network under each scenario.

Exhibit 1 shows a graphical representation of Table 2. Detailed evacuation times by modeled zone and scenario run are provided in Attachment C, and averaged maximum evacuation times by scenario are summarized in Attachment D.

Table 2. Evacuation Modeling Scenarios and Evacuation Time Summary

Scenario	Total Evacuation Vehicles			Evacuation Time (Minutes) by Area		Maximum Evacuation Time by Scenario (H:MM)	Average Evacuation Time by Scenario (H:MM)
	Existing Areas	Ventura Ranch Farmworker Housing Project Area	Total	Existing Areas	Ventura Ranch Farmworker Housing Project Area		
1: Existing 2025	1,095	0	1,095	43.91	0.00	**0:43**	**0:40**
2: Project	0	565	565	0.00	37.98	**0:37**	**0:37**
3: Existing plus Project	1,095	565	1,660	53.53	58.55	**0:58**	**0:53**

Notes: 00.00 = Maximum evacuation time for each scenario (time for last vehicle to leave the network and enter a safe area)

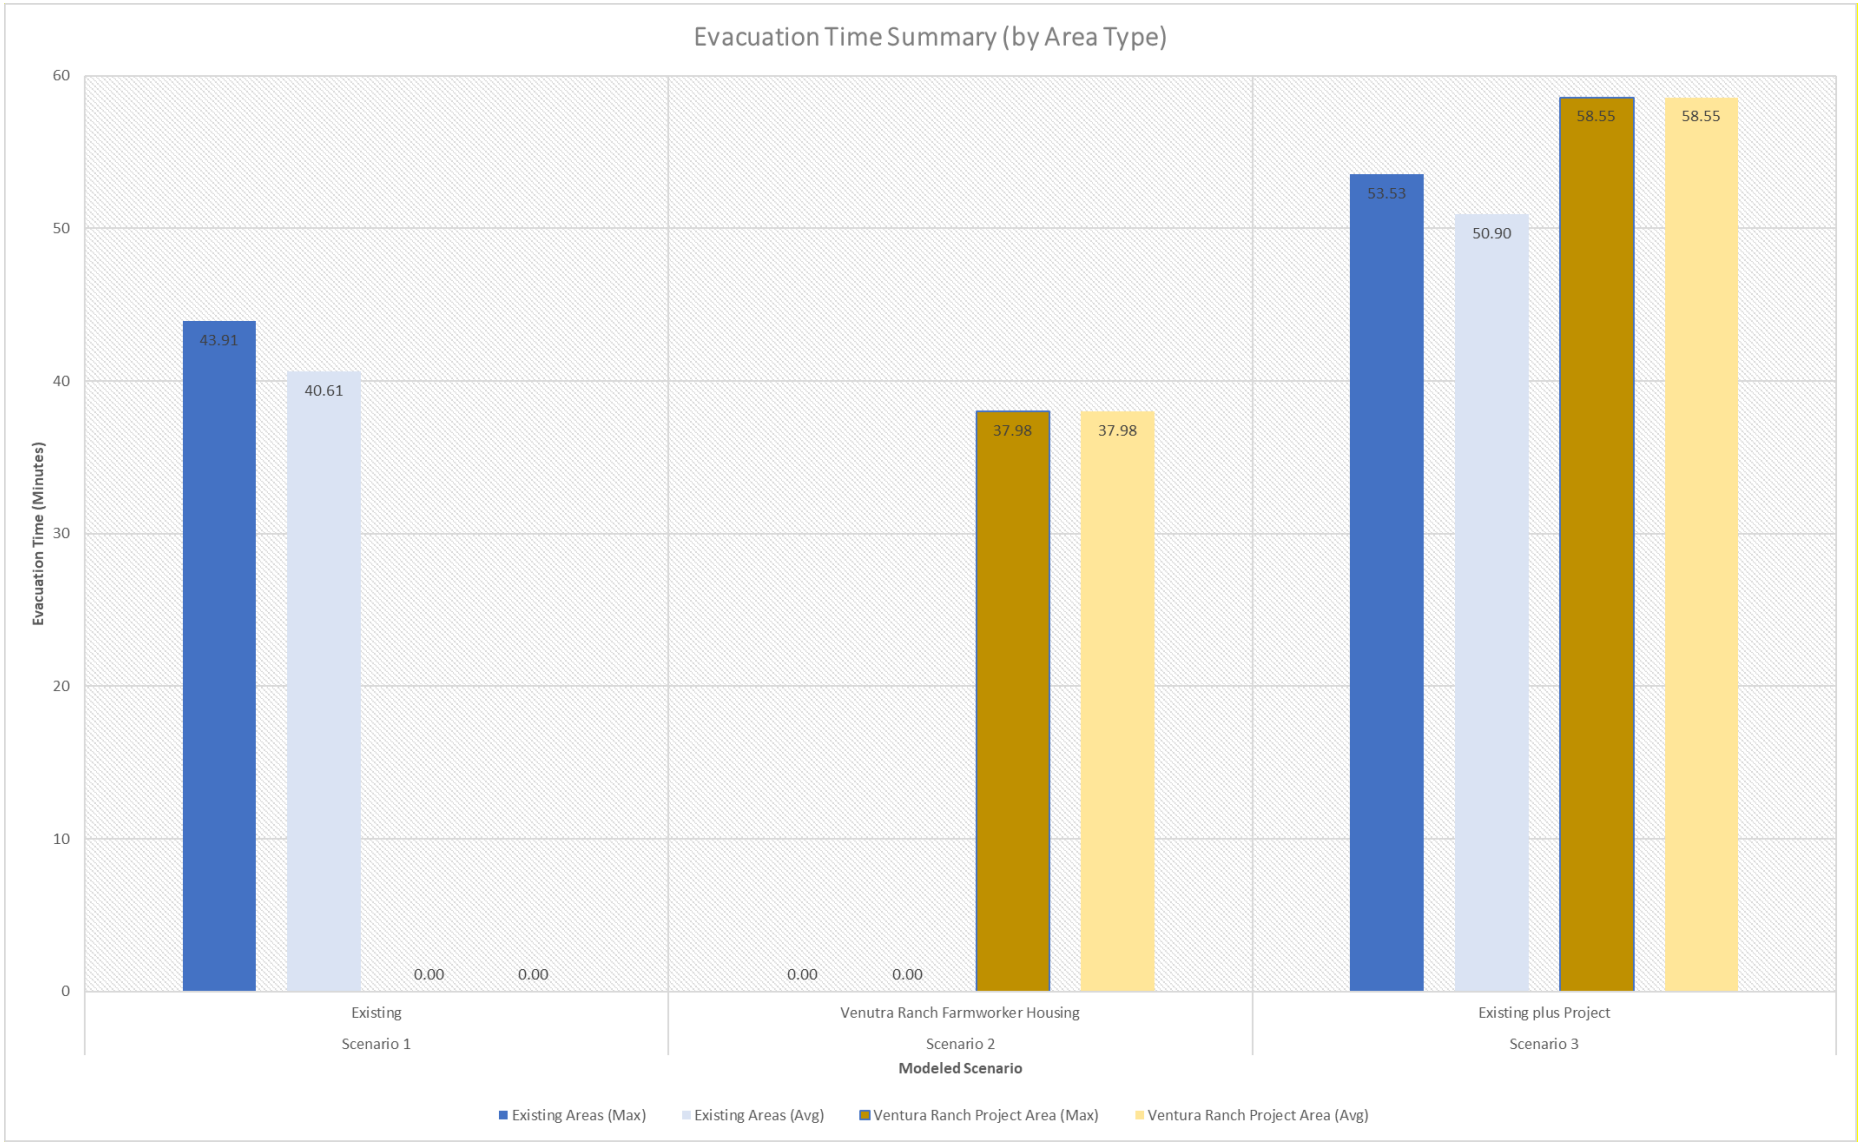

***Exhibit 1** - Evacuation Time Summary*

The following discussion summarizes the results of the evacuation time analysis under each scenario:

Scenario 1 – Existing

Under Existing (Scenario 1) conditions, all existing residential development communities with roadway connections onto Ventura Avenue are included in this scenario, as shown in Figure 3 (Zones B through C). For the purposes of this analysis, it is assumed that the order to evacuate would occur at the beginning of the simulation period, and all vehicles would be evacuated from the study area. It is assumed that all residents in the existing households are at home and the surrounding communities not included in this study area would be under a shelter-in-place order until the communities along Ventura Avenue are evacuated. The simulation results show an evacuation time of almost **44 minutes** to evacuate the 1,095 vehicles from the study area and merge onto the SR-33 mainline under Existing conditions.

Scenario 2 – Ventura Ranch Farmworker Housing (Project only)

Project (Scenario 2) conditions provide an isolated analysis of project only evacuating traffic. As with Existing conditions, it is assumed that the order to evacuate would occur at the beginning of the simulation period, and all vehicles would be evacuated from the study area. It is assumed that all residents on the project site are at home and the surrounding communities not included in this study area would be under a shelter-in-place order until the communities along Ventura Avenue are evacuated. Both accesses to Ventura Avenue from the site are provided in this analysis. The simulation results show an evacuation time of almost **38 minutes** to evacuate the 565 vehicles from the project site and merge onto the SR-33 mainline under Project only conditions.

Scenario 3: Existing plus Project (E+P)

Under Existing plus Project (Scenario 3) conditions, includes all assumptions from the Existing baseline conditions as well as the addition of vehicles from the proposed Project, as shown in Figure 2 (Zones A through C.) As with the prior two scenarios, it is assumed that the order to evacuate would occur at the beginning of the simulation period, and all vehicles would be evacuated from the study area. It is assumed that all residents on the project site and the existing residential developments are at home and the surrounding community not included in the study area would be under a shelter-in-place order until the communities along Ventura Avenue are evacuated. Both accesses to Ventura Avenue from the site are provided in this analysis. The simulation results show an evacuation time of approximately **59 minutes** to evacuate the 1,660 vehicles from the study area and the project site and merge onto the SR-33 mainline under Existing plus Project conditions.

5 Conclusions

As shown by the evacuation times reported above, evacuation of the existing households under Scenario 1 would take just under 1 hour (44 minutes).

Modeled evacuation of the Ventura Ranch Project only (without the surrounding existing or planned developments) under Scenario 2 would take approximately 44 minutes. Accounting for evacuating traffic from existing zones within the study area increases the Project zone's (Zone A) maximum evacuating time to almost 58 minutes under Scenario 3, as shown in the Evacuation Time by Area summary table in Attachment D.

The addition of Ventura Ranch Project traffic to existing traffic during an evacuation event was shown to increase maximum evacuation times in the area by approximately 15 minutes, from almost 44 minutes (without the Ventura Ranch Project) to 59 minutes with the addition of Project traffic.

Attachment D further details the maximum evacuation times from each zone.

The main "pinch-points", or intersections where heavy traffic congestion occurs, were observed at most unsignalized intersections from minor street approaches toVentura Avenue. Highest evacuation times generally occurred from zones further downstream. As vehicles evacuating from the northernmost areas (e.g., the community of Norway Drive) enter Crooked Palm Road, vehicles attempting to make an eastbound right movement do not have priority against free-flowing traffic along Ventura Avenue. To alleviate gridlock conditions at these minor street approaches to Ventura Avenue, the following recommendations are provided:

- ***Recommendation A***: Deploy a police unit or flagger stationed at existing main residential connector roadways such as Norway Drive, Fraser Lane, and Barnes Drive; and the main Project site driveway, to direct traffic from the existing surrounding communities and Project site, facilitating the flow of vehicles onto the Ventura Avenue.[4]
- ***Recommendation B:*** As all vehicles within Zone B filter south to Norway Drive under existing conditions, the additional connection of Floral Drive south into the project site does provide an additional egress for residents in the Norway Drive community to the north, and provides the Project with an additional egress point out of the Project site. However, it is recommended that future connectivity of Floral Drive north to Canada Larga Road should be considered as it would further alleviate the load on internal streets filtering out onto Ventura Avenue, and provide direct connectivity to the Canada Larga Road interchange at SR-33.

Although conservative assumptions were made when developing the model for the study area, evacuation of the project along with the surrounding communities will inevitably be a time intensive process. These modeling assumptions assume a worst-case scenario where each dwelling unit is assumed to have an average of 1.97 vehicles, the project site is parked at maximum capacity, and all vehicles are directed to evacuate from the study area immediately.

Methods to improve evacuation times and conditions are possible through measures including early warning systems, additional traffic control, and instructions from the Emergency Operations Center (EOC) dictating

[4] This recommendation also applies to all stop-controlled intersections to Ventura Avenue in the study area, where feasible.

mandatory evacuation orders to specific high-risk areas and/or shelter-in-place orders to lower-risk areas. Risk to nearby development, including the Ventura Ranch Farmworker Housing Project and existing and planned communities, is assessed on a regular basis in a wildfire event. Hours or days of lead time may also be available to assess risk and make evacuation determinations, which would facilitate a phased evacuation.

The evacuation simulations run for the purposes of this analysis are intended to provide a representative model of a fire evacuation event under various project scenarios. As noted in Chapter 2, creating models that account for all permutations of possible variables would be extremely resource intensive. The amount of time needed to evacuate the Project varies by the type of incident, the number of evacuation routes utilized, the amount of mobilization time, actual areas at risk, and other factors. Further, the peak occupancy as assumed in the model, including the vehicle occupancy assumption of approximately 1.97 vehicles per household, would typically not occur if given the order to evacuate immediately. Additionally, drifting smoke, awareness of the risk, road closures, or other factors often result in people avoiding the area in a fire event.

This report is also intended to serve as guidance for future evacuation planning in this region. For example, resources for additional traffic control can be targeted to the areas noted above where “pinch-points” were observed to improve flow through intersections. Additionally, a targeted approach to phase evacuation by level of risk of each zone to minimize the size of the area being evacuated at one time would further reduce the evacuation time estimates.

The Project would provide adequate egress along the two (2) direct evacuation routes from the project driveways to Ventura Avenue, with an additional (1) gated egress through the community to the north to Norway Drive and back to Ventura Avenue. To provide a conservative analysis, additional routes of egress from the study area were not assumed to be available, including use of other private or unpaved (dirt) roadways south of the project site.

Notes:

1 Sizes of the existing surrounding land uses were determined from the most recent available data from Parcel Quest and the U.S. Census Bureau and cross-referenced with aerial observations using Google Earth.

2 Average Vehicle Ownership Assumptions:

- Surrounding residential land uses (w/"DU" [dwelling unit] as unit) use a 1.97 vehicles/unit rate to determine number of evacuating vehicles per average vehicles/household rate from Census Tract, Ventura County CCD, and Ventura City (2023)
- Ventura Ranch Farmworker Housing (Project) utilizes total provided parking as tabulated in the Project Site Plan (see Figure 2) to determine number of evacuating vehicles.

Appendix B
Federal Preparedness Resources

Additional Items to Consider Adding to an Emergency Supply Kit:

- ❑ **Prescription medications and glasses**
- ❑ **Infant formula and diapers**
- ❑ **Pet food and extra water for your pet**
- ❑ **Important family documents such as copies of insurance policies, identification and bank account records in a waterproof, portable container**
- ❑ **Cash or traveler's checks and change**
- ❑ **Emergency reference material such as a first aid book or information from www.ready.gov**
- ❑ **Sleeping bag or warm blanket for each person. Consider additional bedding if you live in a cold-weather climate.**
- ❑ **Complete change of clothing including a long sleeved shirt, long pants and sturdy shoes. Consider additional clothing if you live in a cold-weather climate.**
- ❑ **Household chlorine bleach and medicine dropper** – When diluted nine parts water to one part bleach, bleach can be used as a disinfectant. Or in an emergency, you can use it to treat water by using 16 drops of regular household liquid bleach per gallon of water. Do not use scented, color safe or bleaches with added cleaners.
- ❑ **Fire Extinguisher**
- ❑ **Matches in a waterproof container**
- ❑ **Feminine supplies and personal hygiene items**
- ❑ **Mess kits, paper cups, plates and plastic utensils, paper towels**
- ❑ **Paper and pencil**
- ❑ **Books, games, puzzles or other activities for children**

Ready

Prepare. Plan. Stay Informed.®

Emergency Supply List

FEMA

www.ready.gov

Recommended Items to Include in a Basic Emergency Supply Kit:

- **Water, one gallon of water per person per day for at least three days, for drinking and sanitation**
- **Food, at least a three-day supply of non-perishable food**
- **Battery-powered or hand crank radio and a NOAA Weather Radio with tone alert and extra batteries for both**
- **Flashlight and extra batteries**
- **First aid kit**
- **Whistle to signal for help**
- **Dust mask, to help filter contaminated air and plastic sheeting and duct tape to shelter-in-place**
- **Moist towelettes, garbage bags and plastic ties for personal sanitation**
- **Wrench or pliers to turn off utilities**
- **Can opener for food (if kit contains canned food)**
- **Local maps**

Through its *Ready* Campaign, the Federal Emergency Management Agency educates and empowers Americans to take some simple steps to prepare for and respond to potential emergencies, including natural disasters and terrorist attacks. *Ready* asks individuals to do three key things: get an emergency supply kit, make a family emergency plan, and be informed about the different types of emergencies that could occur and their appropriate responses.

All Americans should have some basic supplies on hand in order to survive for at least three days if an emergency occurs. Following is a listing of some basic items that every emergency supply kit should include. However, it is important that individuals review this list and consider where they live and the unique needs of their family in order to create an emergency supply kit that will meet these needs. Individuals should also consider having at least two emergency supply kits, one full kit at home and smaller portable kits in their workplace, vehicle or other places they spend time.

BE SMART. TAKE PART. CREATE YOUR FAMILY EMERGENCY COMMUNICATION PLAN

Join with others to prepare for emergencies and participate in America's PrepareAthon! | ready.gov/prepare

Creating your *Family Emergency Communication Plan* starts with one simple question: "What if?"

"What if something happens and I'm not with my family?" "Will I be able to reach them?" "How will I know they are safe?" "How can I let them know I'm OK?" During a disaster, you will need to send and receive information from your family.

Communication networks, such as mobile phones and computers, could be unreliable during disasters, and electricity could be disrupted. Planning in advance will help ensure that all the members of your household—including children and people with disabilities and others with access and functional needs, as well as outside caregivers—know how to reach each other and where to meet up in an emergency. Planning starts with three easy steps:

1. COLLECT.

Create a paper copy of the contact information for your family and other important people/offices, such as medical facilities, doctors, schools, or service providers.

2. SHARE.

Make sure everyone carries a copy in his or her backpack, purse, or wallet. If you complete your *Family Emergency Communication Plan* online at ready.gov/make-a-plan, you can print it onto a wallet-sized card. You should also post a copy in a central location in your home, such as your refrigerator or family bulletin board.

3. PRACTICE.

Have regular household meetings to review and practice your plan.

TEXT IS BEST!

If you are using a mobile phone, a text message may get through when a phone call will not. This is because a text message requires far less bandwidth than a phone call. Text messages may also save and then send automatically as soon as capacity becomes available.

The following sections will guide you through the process to create and practice your *Family Emergency Communication Plan*.

HOUSEHOLD INFORMATION

Write down phone numbers and email addresses for everyone in your household. Having this important information written down will help you reconnect with others in case you don't have your mobile device or computer with you or if the battery runs down. If you have a household member(s) who is Deaf or hard of hearing, or who has a speech disability and uses traditional or video relay service (VRS), include information on how to connect through relay services on a landline phone, mobile device, or computer.

SCHOOL, CHILDCARE, CAREGIVER, AND WORKPLACE EMERGENCY PLANS

Because a disaster can strike during school or work hours, you need to know their emergency response plans and how to stay informed. Discuss these plans with children, and let them know who could pick them up in an emergency. Make sure your household members with phones are signed up for alerts and warnings from their school, workplace, and/or local government. To find out more about how to sign up, see *Be Smart. Know Your Alerts and Warnings* at http://1.usa.gov/1BDloze. For children without mobile phones, make sure they know to follow instructions from a responsible adult, such as a teacher or principal.

OUT-OF-TOWN CONTACT

It is also important to identify someone outside of your community or State who can act as a central point of contact to help your household reconnect. In a disaster, it may be easier to make a long-distance phone call than to call across town because local phone lines can be jammed.

EMERGENCY MEETING PLACES

Decide on safe, familiar places where your family can go for protection or to reunite. Make sure these locations are accessible for household members with disabilities or access and functional needs. If you have pets or service animals, think about animal-friendly locations. Identify the following places:

- ☐ *Indoor*: If you live in an area where tornadoes, hurricanes, or other high-wind storms can happen, make sure everyone knows where to go for protection. This could be a small, interior, windowless room, such as a closet or bathroom, on the lowest level of a sturdy building, or a tornado safe room or storm shelter.
- ☐ *In your neighborhood*: This is a place in your neighborhood where your household members will meet if there is a fire or other emergency and you need to leave your home. The meeting place could be a big tree, a mailbox at the end of the driveway, or a neighbor's house.
- ☐ *Outside of your neighborhood*: This is a place where your family will meet if a disaster happens when you're not at home and you can't get back to your home. This could be a library, community center, house of worship, or family friend's home.

- [ ] *Outside of your town or city*: Having an out-of-town meeting place can help you reunite if a disaster happens and:

  - You cannot get home or to your out-of-neighborhood meeting place; or
  - Your family is not together and your community is instructed to evacuate the area.

  This meeting place could be the home of a relative or family friend. Make sure everyone knows the address of the meeting place and discuss ways you would get there.

OTHER IMPORTANT NUMBERS AND INFORMATION

You should also write down phone numbers for emergency services, utilities, service providers, medical providers, veterinarians, insurance companies, and other services.

- [ ] Make copies of your *Family Emergency Communication Plan* for each member of the household to carry in his or her wallet, backpack, or purse. Post a copy in a central place at home. Regularly check to make sure your household members are carrying their plan with them.
- [ ] Enter household and emergency contact information into all household members' mobile phones or devices.
- [ ] Store at least one emergency contact under the name "In Case of Emergency" or "ICE" for all mobile phones and devices. This will help someone identify your emergency contact if needed. Inform your emergency contact of any medical issues or other requirements you may have.
- [ ] Create a group list on all mobile phones and devices of the people you would need to communicate with if there was an emergency or disaster.
- [ ] Make sure all household members and your out-of-town contact know how to text if they have a mobile phone or device, or know alternative ways to communicate if they are unable to text.
- [ ] Read *Be Smart. Know Your Alerts and Warnings* at http://1.usa.gov/1BDloze and sign up to receive emergency information.

Once you have completed your *Family Emergency Communication Plan*, made copies for all the members of your household, and discussed it, it's time to practice!

Here are some ideas for practicing your plan:

- [ ] Practice texting and calling. Have each person practice sending a text message or calling your out-of-town contact and sending a group text to your mobile phone group list.
- [ ] Discuss what information you should send by text. You will want to let others know you are safe and where you are. Short messages like "I'm OK. At library" are good.

- [ ] Talk about who will be the lead person to send out information about the designated meeting place for the household.
- [ ] Practice gathering all household members at your indoor and neighborhood emergency meeting places. Talk about how each person would get to the identified out-of-neighborhood and out-of-town meeting places. Discuss all modes of transportation, such as public transportation, rail, and para-transit for all family members, including people with disabilities and others with access and functional needs.
- [ ] Regularly have conversations with household members and friends about the plan, such as whom and how to text or call, and where to go.
- [ ] To show why it's important to keep phone numbers written down, challenge your household members to recite important phone numbers from memory—now ask them to think about doing this in the event of an emergency.
- [ ] Make sure everyone, including children, knows how and when to call 911 for help. You should only call 911 when there is a life-threatening emergency.
- [ ] Review, update, and practice your *Family Emergency Communication Plan* at least once a year, or whenever any of your information changes.

To help start the conversation or remind your family why you are taking steps to prepare and practice, you may want to watch the 4-minute video, *It Started Like Any Other Day*, about families who have experienced disaster, at www.youtube.com/watch?v=w_omgt3MEBs. Click on the closed captioning (CC) icon on the lower right to turn on the captioning.

After you practice, talk about how it went. What worked well? What can be improved? What information, if any, needs to be updated? If you make updates, remember to print new copies of the plan for everyone.

OTHER IMPORTANT TIPS FOR COMMUNICATING IN DISASTERS[1]

- [ ] Text is best when using a mobile phone, but if you make a phone call, keep it brief and convey only vital information to emergency personnel and/or family or household members. This will minimize network congestion, free up space on the network for emergency communications, and conserve battery power. Wait 10 seconds before redialing a number. If you redial too quickly, the data from the handset to the cell sites do not have enough time to clear before you've re-sent the same data. This contributes to a clogged network.
- [ ] Conserve your mobile phone battery by reducing the brightness of your screen, placing your phone in airplane mode, and closing apps you do not need. Limit watching videos and playing video games to help reduce network congestion.
- [ ] Keep charged batteries, a car phone charger, and a solar charger available for backup power for your mobile phone, teletypewriters (TTYs), amplified phones, and caption phones. If you charge your phone in your car, be sure the car is in a well-ventilated area (e.g., not in a closed garage) to avoid life-threatening carbon monoxide poisoning.

[1] Federal Communications Commission, Public Safety and Homeland Security Bureau. (n.d.) *Tips for communicating in an emergency.* Retrieved from http://transition.fcc.gov/pshs/emergency-information/tips.html

- [ ] If driving, do not text, read texts, or make a call without a hands-free device.
- [ ] Maintain a household landline and analog phone (with battery backup if it has a cordless receiver) that can be used when mobile phone service is unavailable. Those who are Deaf or hard of hearing, or who have speech disabilities and use devices and services that depend on digital technology (e.g., VRS, Internet Protocol [IP] Relay, or captioning) should have an analog phone (e.g., TTY, amplified phone, or caption phone) with battery backup in case Internet or mobile service is down.
- [ ] If you evacuate and have a call-forwarding feature on your home phone, forward your home phone number to your mobile phone number.
- [ ] Use the Internet to communicate by email, Twitter, Facebook, and other social media networks. These communication channels allow you to share information quickly with a widespread audience or to find out if loved ones are OK. The Internet can also be used for telephone calls through Voice over Internet Protocol. For those who are Deaf or hard of hearing, or who have speech disabilities, you can make calls through your IP Relay provider.
- [ ] If you do not have a mobile phone, keep a prepaid phone card to use if needed during or after a disaster.
- [ ] Use a pay phone if available. It may have less congestion because these phones don't rely on electricity or mobile networks. In some public places, you may be able to find a TTY that can be used by those who are Deaf or hard of hearing, or who have speech disabilities.

Plan of Action

1. The disasters most likely to affect our household are:

2. What are the escape routes from our home?

3. If separated during an emergency, what is our meeting place near our home?

4. If we cannot return home or are asked to evacuate, what is our meeting place outside of our neighborhood?

_____

What is our route to get there and an alternate route, if the first route is impassible?

_____

_____

5. In the event our household is separated or unable to communicate with each other, our emergency contact outside of our immediate area is:

Name	Home Phone	Cell Phone	Email:
_____	_____	_____	_____

After a disaster, let your friends and family know you are okay by registering at "Safe and Well" at https://safeandwell.communityos.org/cms// or by calling 1-800-733-2767. You can also give them a call, send a quick text or update your status on social networking sites.

6. If at school/daycare, our child(ren) will be evacuated to:

Child's Name:	Evacuation Site (address and contact info):
_____	_____
_____	_____
_____	_____
_____	_____

7. Our plan for people in our household with a disability or special need is:

Person's Name:	Plan:
_____	_____
_____	_____

8. During certain emergencies local authorities may direct us to "shelter in place" in our home. An accessible, safe room where we can go, seal windows, vents and doors and listen to emergency broadcasts for instructions, is:

_____

9. Family Member Responsibilities in the Event of a Disaster

Task	Description	Family Member Responsible
Disaster Kit*	Stock the disaster kit and take it if evacuation is necessary. Include items you might want to take to an evacuation shelter. Remember to include medications and eye glasses.	
Be informed	Maintain access to NOAA or local radio, TV, email or text alerts for important and current information about disasters.	
Family Medical Information	Make sure the household medical information is taken with us if evacuation is necessary.	
Financial Information	Obtain copies of bank statements and cash in the event ATMs and credit cards do not work due to power outages. Bring copies of utility bills as proof of residence in applying for assistance.	
Pet Information	Evacuate our pet(s), keep a phone list of pet-friendly motels and animal shelters, and assemble and take the pet disaster kit.	
Sharing and Maintaining the Plan	Share the completed plan with those who need to know. Meet with household members every 6 months or as needs change to update household plan.	

**What supplies and records should go in your disaster kit? Visit www.redcross.org*

10. Other information, if not able to be included above.

Congratulations on completing your family disaster plan! Please tell others: "We've made a family disaster plan and you can, too, with help from the American Red Cross."

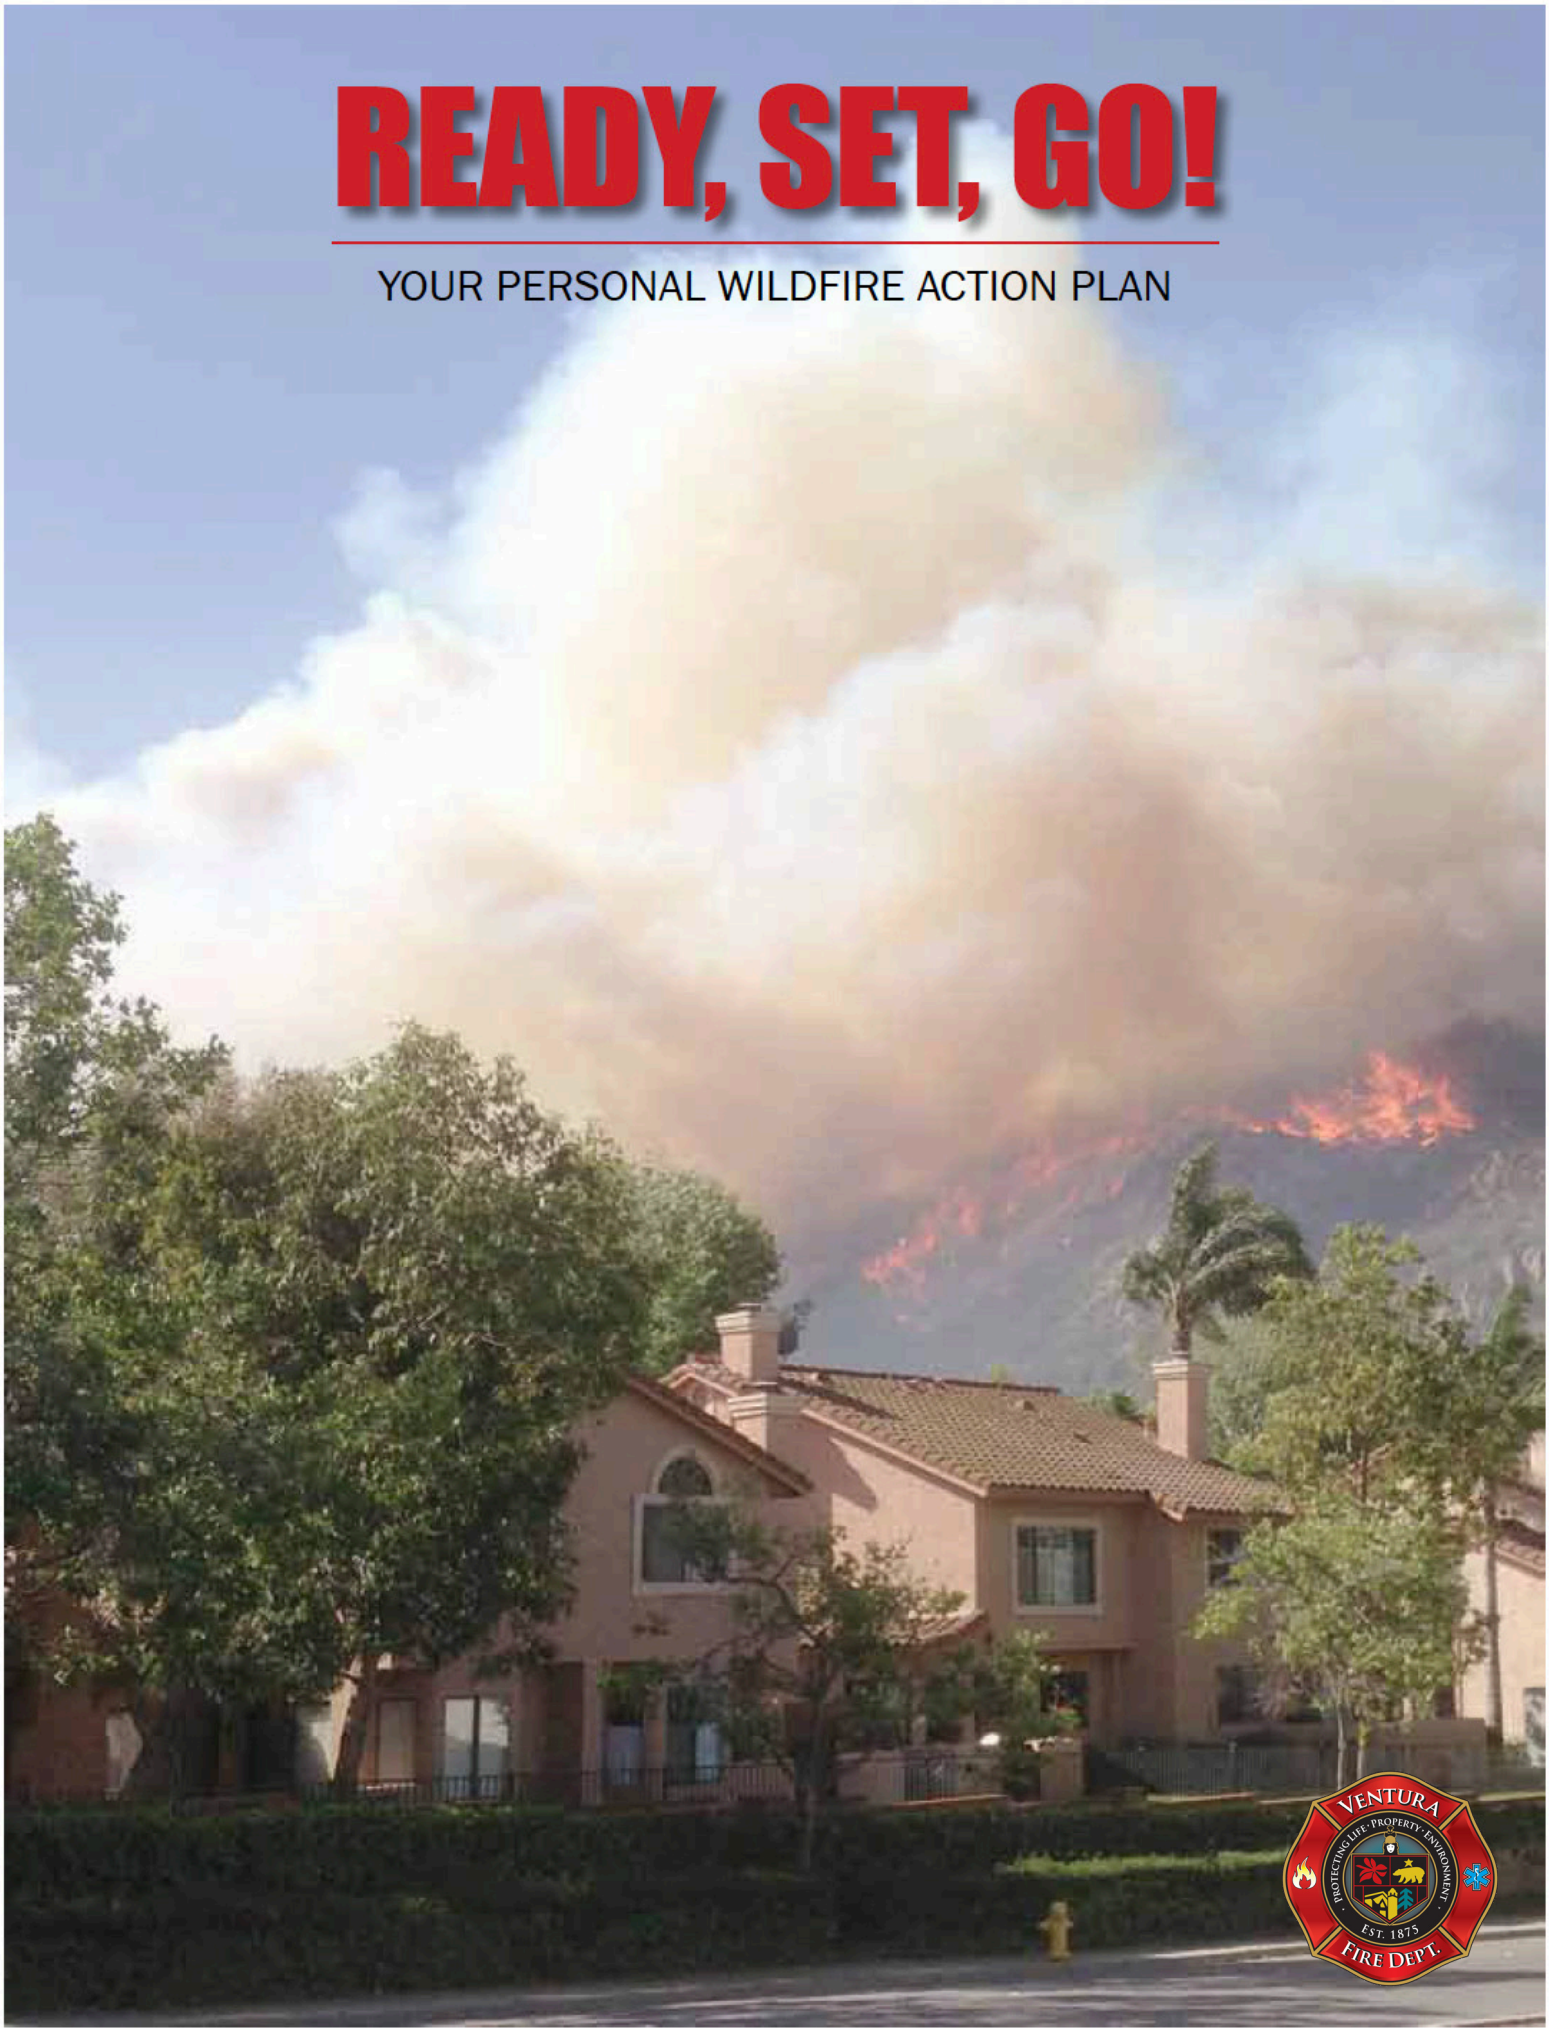
Local and State Preparedness Resources

READY, SET, GO!

YOUR PERSONAL WILDFIRE ACTION PLAN



READY, SET, GO!

Wildfire Action Plan

Saving Lives and Property through Advanced Planning

Fire season is now a year-round reality in Ventura County. This means that both firefighters and residents must be on heightened alert for the threat of wildfire at all times.

Firefighters train constantly and make countless preparations to be ready for a wildfire. Residents need to prepare as well. Successfully planning for a wildfire requires you to take personal responsibility for protecting yourself, your family and your property.

The Ventura Fire Department takes every precaution to help protect you and your property from a wildfire. The reality is, during a major wildfire, there will simply not be enough fire engines or firefighters to defend every home. You must become part of the solution.

If your home borders a natural area, what firefighters refer to as the Wildland Urban Interface, you are at increased risk during a wildfire. If you live within one mile of a natural area, you live in the Ember Zone. Homes in the Ember Zone are at risk of wind-driven embers from a wildfire. Entire neighborhoods have been destroyed by fires started by embers, not the wildfire itself.

This publication will help guide you through the process of making your home resistant to wildfires and preparing your family to leave early and safely. We call this process, "Ready, Set, Go!"

You will learn about the Ember Zone and how to retrofit your home with ignition resistant features. We will show you the importance of having defensible space around your home, and the preparations you need to make so you may leave early, evacuating well ahead of the fire.

Fire is a natural part of the beautiful area where we have chosen to live. Wildfires fueled by a build-up of drought-ravaged vegetation and driven by hot, dry winds, are extremely dangerous and almost impossible to control. Many residents have built their homes and landscapes without fully understanding the impact a fire could have on them. This publication will help you prepare your home so you may leave early, confident that you have done everything reasonably possible to protect your home.

It is not a question of if, but rather when, the next wildfire will occur. That is why the most important person protecting your life and property is you. Through advanced planning and preparation, you will dramatically increase your personal safety and the survivability of your property.

I hope you will find the information on the following pages helpful as you prepare your home and family for a wildfire. Now, get ready, get set, and go!

Go Early Checklist	10
Your Own Wildfire Action Plan	11

This publication was prepared by the Ventura County Fire Department. Special thanks to CALFIRE, Orange County Fire Authority, FireSafe Council, Firewise Communities, and the Institute for Business and Home Safety as well as many other organizations for their contributions to content.

Living in the Wildland Urban Interface and the Ember Zone

Ready, Set, Go! begins with a house that firefighters can defend.

Defensible space works!

If you live next to a natural area, the Wildland Urban Interface, you must provide firefighters with the defensible space they need to protect your home. The buffer zone you create by removing weeds, brush and other vegetation helps to keep the fire away from your home and reduces the risks from flying embers.

A home within one mile of a natural area is in the Ember Zone. Wind-driven embers can attack your home. You and your home must be prepared well before a fire occurs. Ember fires can destroy homes or neighborhoods far from the actual flame front of the wildfire.

What is Defensible Space?

Defensible space is the required space between a structure and the wildland area that, under normal conditions, creates a sufficient buffer to slow or halt the spread of wildfire to a structure. It protects the home from igniting due to direct flame or radiant heat. Defensible space is essential for structure survivability during wildfire conditions.

ZONE ONE

Zone One extends 30 feet out from buildings, structures, decks, etc.

- Remove all dead or dying vegetation.
- Trim tree canopies regularly to keep their branches a minimum of 10 feet from structures and other trees.
- Remove leaf litter (dry leaves/pine needles) from yard, roof and rain gutters.
- Relocate woodpiles or other combustible materials into Zone Two.
- Remove combustible material and vegetation from around and under decks.
- Remove or prune vegetation near windows.
- Remove “ladder fuels” (low-level vegetation that allows the fire to spread from the ground to the tree canopy). Create a separation between low-level vegetation and tree branches. This can be done by reducing the height of low-level vegetation and/or trimming low tree branches.

ZONE TWO

Zone Two extends 30 to 100 feet out from buildings, structures and decks. You can minimize the chance of fire jumping from plant to plant by removing dead material and removing and/or thinning vegetation. The minimum spacing between vegetation is three times the dimension of the plant.

- Remove “ladder fuels.”
- Cut or mow annual grass down to a maximum height of 4 inches.
- Trim tree canopies regularly to keep their branches a minimum of 10 feet from other trees.

What is a Hardened Home?

Construction materials and the quality of the defensible space surrounding it are what gives a home the best chance to survive a wildfire. Embers from a wildfire will find the weak link in your home's fire protection scheme and gain the upper hand because of a small, overlooked or seemingly inconsequential factor. However, there are measures you can take to safeguard your home from wildfire. While you may not be able to accomplish all the measures listed below, each will increase your home's, and possibly your family's, safety and survival during a wildfire.

ROOFS

Roofs are the most vulnerable surface where embers land because they can lodge and start a fire. Roof valleys, open ends of barrel tiles and rain gutters are all points of entry.

EAVES

Embers can gather under open eaves and ignite exposed wood or other combustible material.

VENTS

Embers can enter the attic or other concealed spaces and ignite combustible materials. Vents in eaves and cornices are particularly vulnerable, as are any unscreened vents.

WALLS

Combustible siding or other combustible or overlapping materials provide surfaces or crevices for embers to nestle and ignite.

WINDOWS and DOORS

Embers can enter gaps in doors, including garage doors. Plants or combustible storage near windows can be ignited from embers and generate heat that can break windows and/or melt combustible frames.

BALCONIES and DECKS

Embers can collect in or on combustible surfaces or the undersides of decks and balconies, ignite the material and enter the home through walls or windows.

To harden your home even further, consider protecting your homes with a residential fire sprinkler system. In addition to extinguishing a fire started by an ember that enters your home, it also protects you and your family year-round from any fire that may start in your home.

Tour a Wildfire Ready Home

Home Site and Yard: Ensure you have at least a 100-foot radius of defensible space (cleared vegetation) around your home. Note that even more clearance may be needed for homes in severe hazard areas. This means looking past what you own to determine the impact a common slope or neighbors' yard will have on your property during a wildfire.

Cut dry weeds and grass before noon when temperatures are cooler to reduce the chance of sparking a fire.

Landscape with fire-resistant plants that have a high moisture content and are low-growing.

Keep woodpiles, propane tanks and combustible materials away from your home and other structures such as garages, barns and sheds.

Ensure that trees are far away from power lines.

Roof: Your roof is the most vulnerable part of your home because it can easily catch fire from wind-blown embers. Homes with wood-shake or shingle roofs are at high risk of being destroyed during a wildfire.

Build your roof or re-roof with fire-resistant materials such as composition, metal or tile. Block any spaces between roof decking and covering to prevent ember intrusion.

Clear pine needles, leaves and other debris from your roof and gutters.

Cut any tree branches within ten feet of your roof.

Vents: Vents on homes are particularly vulnerable to flying embers.

All vent openings should be covered with ⅛-inch or smaller metal mesh. Do not use fiberglass or plastic mesh because they can melt and burn.

Attic vents in eaves or cornices should be baffled or otherwise protected to prevent ember intrusion (mesh is not enough).

Windows: Heat from a wildfire can cause windows to break even before the home ignites. This allows burning embers to enter and start internal fires. Single-paned and large windows are particularly vulnerable.

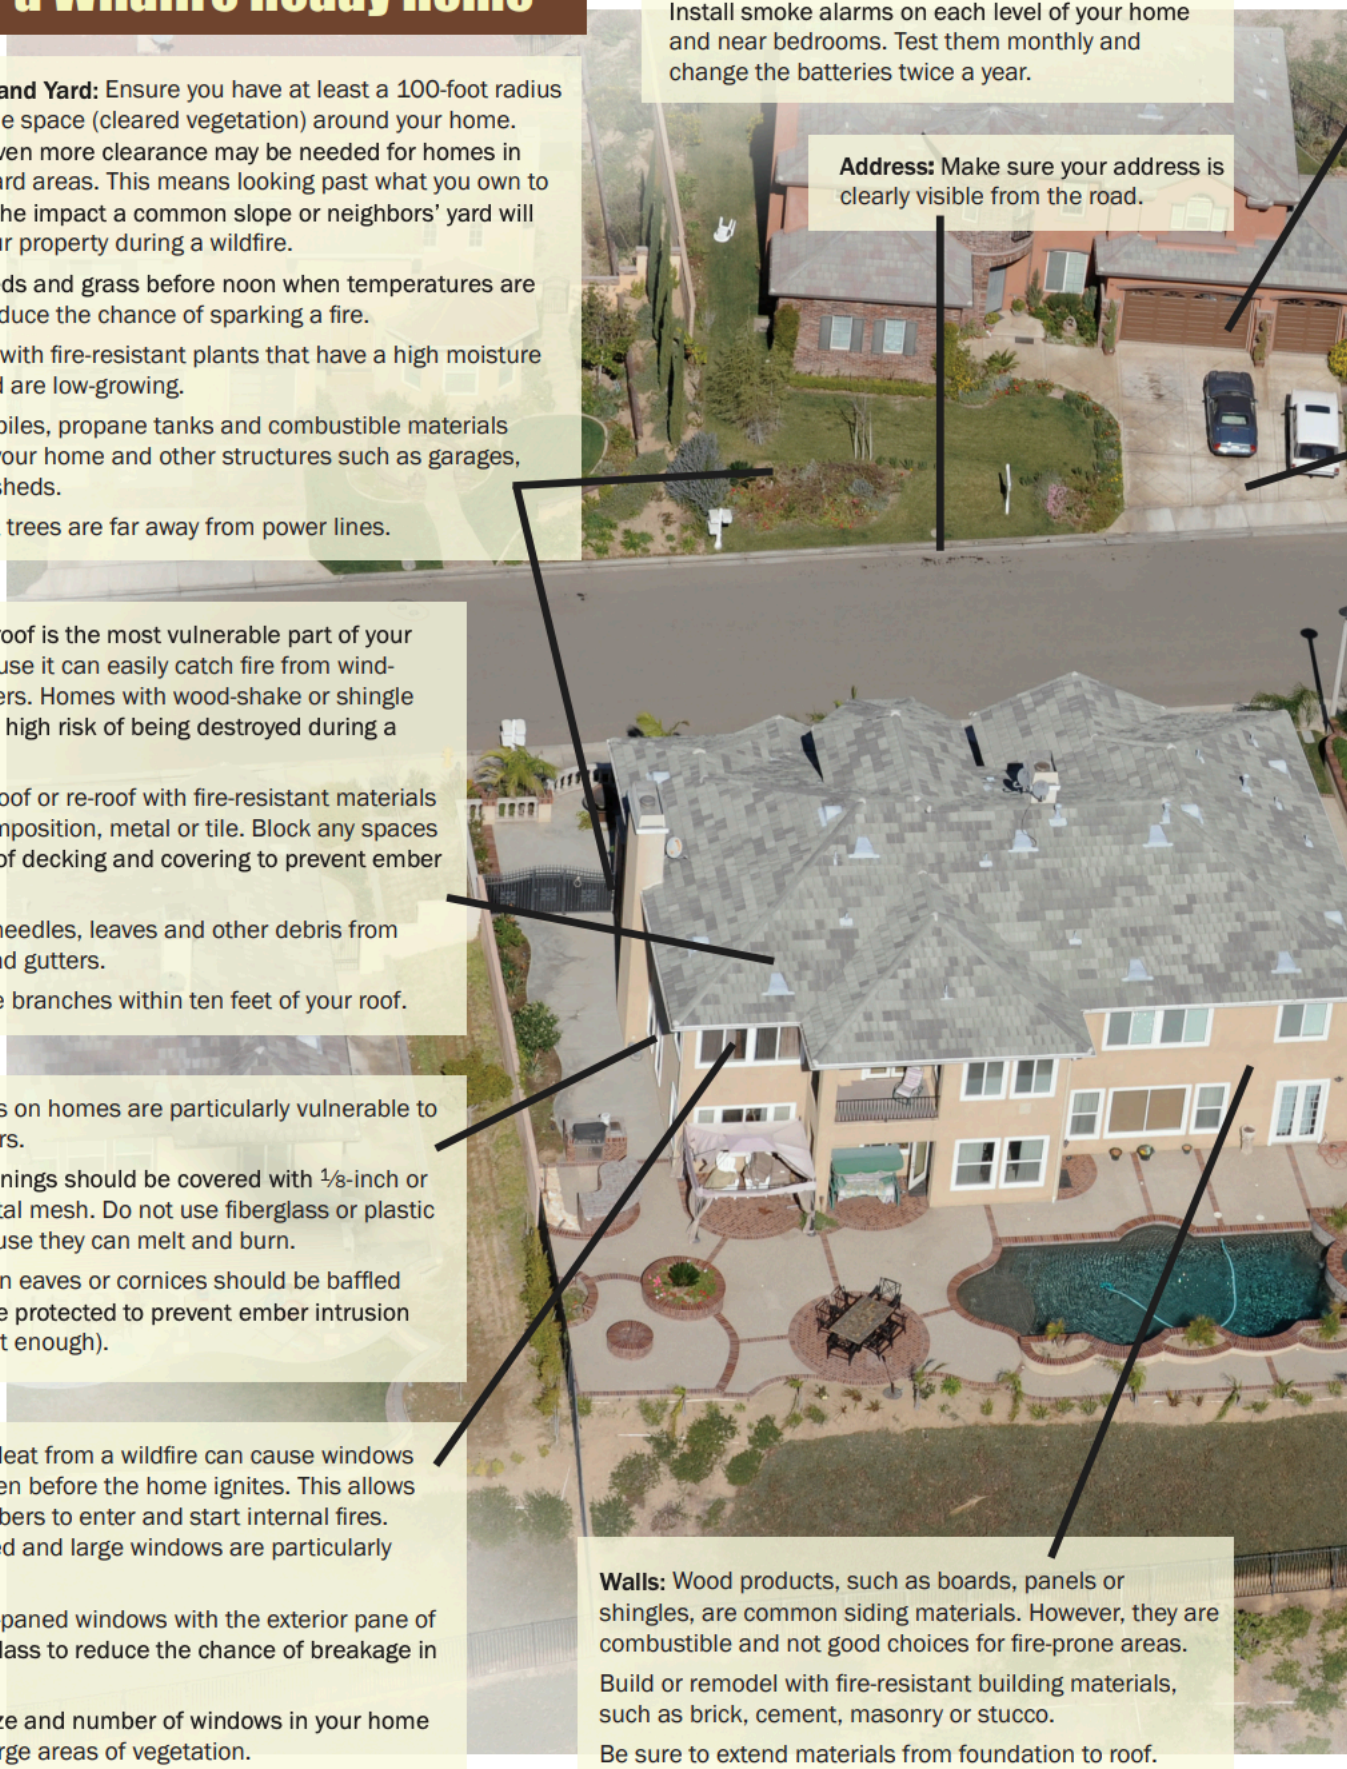
Install dual-paned windows with the exterior pane of tempered glass to reduce the chance of breakage in a fire.

Limit the size and number of windows in your home that face large areas of vegetation.

Inside: Keep working fire extinguishers on hand.

Install smoke alarms on each level of your home and near bedrooms. Test them monthly and change the batteries twice a year.

Address: Make sure your address is clearly visible from the road.



Walls: Wood products, such as boards, panels or shingles, are common siding materials. However, they are combustible and not good choices for fire-prone areas.

Build or remodel with fire-resistant building materials, such as brick, cement, masonry or stucco.

Be sure to extend materials from foundation to roof.

Garage: Have a fire extinguisher and tools such as a shovel, rake, bucket and hoe available for fire emergencies.

Install a solid door with self-closing hinges between living areas and the garage. Install weather stripping around and under door to prevent ember intrusion.

Store all combustibles and flammable liquids away from ignition sources.

Driveways and Access Roads: Driveways should be designed to allow fire and emergency vehicles and equipment to reach your house.

Access roads should have a minimum 10-foot clearance on either side of the traveled section of the roadway and should allow for two-way traffic.

Ensure that all gates open inward and are wide enough to accommodate emergency equipment.

Trim trees and shrubs overhanging the road to a minimum of 13 1/2 feet to allow emergency vehicles to pass.

Non-Combustible Fencing: Make sure to use non-combustible fencing to protect your home during a wildfire.

Non-Combustible Boxed In Eaves: Box in eaves with non-combustible materials to prevent accumulation of embers.

Rain gutters: Screen or enclose rain gutters to prevent accumulation of plant debris.

Water Supply: Have multiple garden hoses that are long enough to reach any area of your home and other structures on your property.

If you have a pool or well, consider a pump.

Deck/Patio Cover: Use heavy timber or non-flammable construction material for decks.

Enclose the underside of balconies and decks with fire-resistant materials to prevent embers from blowing underneath.

Keep your deck clear of combustible items, such as baskets, dried flower arrangements and other debris.

The decking surface must be ignition resistant if it's within 10 feet of the home.

Chimney: Cover your chimney and stovepipe outlets with a non-flammable screen of ¼-inch wire mesh or smaller to prevent embers from escaping and igniting a fire.

Make sure that your chimney is at least 10 feet away from any tree branches.

READY, SET, GO!

Create Your Own Wildfire Action Plan

Now that you've done everything you can to protect your house, it's time to prepare your family. Your **Wildfire Action Plan** must be prepared with all members of your household well in advance of a fire.

Use these checklists to help you prepare your Wildfire Action Plan. Each family's plan will be different, depending on their situation.

Once you finish your plan, rehearse it regularly with your family and keep it in a safe and accessible place for quick implementation.

GET READY

Prepare Your Family

- ☐ Create a **Family Disaster Plan** that includes meeting locations and communication plans and rehearse it regularly. Include in your plan the evacuation of large animals such as horses.
- ☐ Have fire extinguishers on hand and train your family how to use them.
- ☐ Ensure that your family knows where your gas, electric and water main shut-off controls are and how to use them.
- ☐ Plan several different evacuation routes.
- ☐ Designate an emergency meeting location outside the fire hazard area.
- ☐ Assemble an emergency supply kit as recommended by the American Red Cross.
- ☐ Appoint an out-of-area friend or relative as a point of contact so you can communicate with family members who have relocated.
- ☐ Maintain a list of emergency contact numbers posted near your phone and in your emergency supply kit.
- ☐ Keep an extra emergency supply kit in your car in case you can't get to your home because of fire.
- ☐ Have a portable radio or scanner so you can stay updated on the fire.

GET SET | As the Fire Approaches

- [ ] Evacuate as soon as you are set!
- [ ] Alert family and neighbors.
- [ ] Dress in appropriate clothing (i.e., clothing made from natural fibers, such as cotton, and work boots). Have goggles and a dry bandana or particle mask handy.
- [ ] Ensure that you have your emergency supply kit on hand that includes all necessary items, such as a battery powered radio, spare batteries, emergency contact numbers, and ample drinking water.
- [ ] Stay tuned to your TV or local radio stations for updates, or check the fire department website.
- [ ] Remain close to your house, drink plenty of water and keep an eye on your family and pets until you are ready to leave.

INSIDE CHECKLIST

- [ ] Shut all windows and doors, leaving them unlocked.
- [ ] Remove flammable window shades and curtains and close metal shutters.
- [ ] Remove lightweight curtains.
- [ ] Move flammable furniture to the center of the room, away from windows and doors.
- [ ] Shut off gas at the meter. Turn off pilot lights.
- [ ] Leave your lights on so firefighters can see your house under smoky conditions.
- [ ] Shut off the air conditioning.

OUTSIDE CHECKLIST

- [ ] Gather up flammable items from the exterior of the house and bring them inside (e.g., patio furniture, children's toys, door mats, etc.) or place them in your pool.
- [ ] Turn off propane tanks.
- [ ] Don't leave sprinklers on or water running - they can waste critical water pressure.
- [ ] Leave exterior lights on.
- [ ] Back your car into the driveway. Shut doors and roll up windows.
- [ ] Have a ladder available.
- [ ] Patrol your property and extinguish all small fires until you leave.
- [ ] Seal attic and ground vents with pre-cut plywood or commercial seals if time permits.

IF YOU ARE TRAPPED: SURVIVAL TIPS

- [ ] Shelter away from outside walls.
- [ ] Bring garden hoses inside house so embers don't destroy them.
- [ ] Patrol inside your home for spot fires and extinguish them.
- [ ] Wear long sleeves and long pants made of natural fibers such as cotton.
- [ ] Stay hydrated.
- [ ] Ensure you can exit the home if it catches fire (remember if it's hot inside the house, it is four to five times hotter outside).
- [ ] Fill sinks and tubs for an emergency water supply.
- [ ] Place wet towels under doors to keep smoke and embers out.
- [ ] After the fire has passed, check your roof and extinguish any fires, sparks or embers.
- [ ] Check inside the attic for hidden embers.
- [ ] Patrol your property and extinguish small fires.
- [ ] If there are fires that you can not extinguish with a small amount of water or in a short period of time, call 9-1-1.

Go! | Early!

By leaving early, you give your family the best chance of surviving a wildfire. You also help firefighters by keeping roads clear of congestion, enabling them to move more freely and do their job.

WHEN TO LEAVE

Leave early enough to avoid being caught in fire, smoke or road congestion. Don't wait to be told by authorities to leave. In an intense wildfire, they may not have time to knock on every door. If you are advised to leave, don't hesitate!

WHERE TO GO

Leave to a predetermined location (it should be a low-risk area, such as a well-prepared neighbor or relative's house, a Red Cross shelter or evacuation center, motel, etc.)

HOW TO GET THERE

Have several travel routes in case one route is blocked by the fire or by emergency vehicles and equipment. Choose an escape route away from the fire.

WHAT TO TAKE

Take your emergency supply kit containing your family and pet's necessary items.

EMERGENCY SUPPLIES

The American Red Cross recommends every family have an emergency supply kit assembled long before a wildfire or other emergency occurs. Use the checklist below to help assemble yours. For more information on emergency supplies, visit the American Red Cross Web site at www.redcross.org.

- ☐ Three-day supply of water (one gallon per person per day).
- ☐ Non-perishable food for all family members and pets (three-day supply).
- ☐ First aid kit.
- ☐ Flashlight, battery-powered radio, and extra batteries.
- ☐ An extra set of car keys, credit cards, cash or traveler's checks.
- ☐ Sanitation supplies.
- ☐ Extra eyeglasses or contact lenses.
- ☐ Important family documents and contact numbers.
- ☐ Map marked with evacuation routes.
- ☐ Prescriptions or special medications.
- ☐ Family photos and other irreplaceable items.
- ☐ Easily carried valuables.
- ☐ Personal computers (information on hard drives and disks).
- ☐ Chargers for cell phones, laptops, etc.

Note: Keep a pair of old shoes and a flashlight handy in case of a sudden evacuation at night.

Write up your Wildfire Action Plan and post it in a location where every member of your family can see it. Rehearse it with your family.

My Personal Wildfire Action Plan

During High Fire Danger days in your area, monitor your local media for information on brush fires and be ready to implement your plan. Hot, dry and windy conditions create the perfect environment for a wildfire.

VC ALERT

EMERGENCY NOTIFICATION SYSTEM

VC Alert is an emergency notification system that may be used to deliver emergency alerts when there is a threat to the health or safety of Ventura County residents.

In addition to emergency information, you may:

- ✓ Choose the location you want to be contacted about — your home, your parents' home, your workplace and your child's school.
- ✓ Receive alerts on your home phone, cellular phone, work phone, email, text messaging, facsimile or instant messaging.

For more information and to register, please visit www.vcalert.org or contact us at (805) 648-9283 or via email at vc.alert@ventura.org

Living in the Wildland Urban Interface and the Ember Zone

Ready, Set, Go! begins with a house that firefighters can defend.

Defensible space works!

If you live next to a natural area, the Wildland Urban Interface, you must provide firefighters with the defensible space they need to protect your home. The buffer zone you create by removing weeds, brush and other vegetation helps to keep the fire away from your home and reduces the risks from flying embers.

A home within one mile of a natural area is in the Ember Zone. Wind-driven embers can attack your home. You and your home must be prepared well before a fire occurs. Ember fires can destroy homes or neighborhoods far from the actual flame front of the wildfire.

What is Defensible Space?

Defensible space is the required space between a structure and the wildland area that, under normal conditions, creates a sufficient buffer to slow or halt the spread of wildfire to a structure. It protects the home from igniting due to direct flame or radiant heat. Defensible space is essential for structure survivability during wildfire conditions.

ZONE ONE

Zone One extends 30 feet out from buildings, structures, decks, etc.

- Remove all dead or dying vegetation.
- Trim tree canopies regularly to keep their branches a minimum of 10 feet from structures and other trees.
- Remove leaf litter (dry leaves/pine needles) from yard, roof and rain gutters.
- Relocate woodpiles or other combustible materials into Zone Two.
- Remove combustible material and vegetation from around and under decks.
- Remove or prune vegetation near windows.
- Remove “ladder fuels” (low-level vegetation that allows the fire to spread from the ground to the tree canopy). Create a separation between low-level vegetation and tree branches. This can be done by reducing the height of low-level vegetation and/or trimming low tree branches.

ZONE TWO

Zone Two extends 30 to 100 feet out from buildings, structures and decks. You can minimize the chance of fire jumping from plant to plant by removing dead material and removing and/or thinning vegetation. The minimum spacing between vegetation is three times the dimension of the plant.

- Remove “ladder fuels.”
- Cut or mow annual grass down to a maximum height of 4 inches.
- Trim tree canopies regularly to keep their branches a minimum of 10 feet from other trees.

What is a Hardened Home?

Construction materials and the quality of the defensible space surrounding it are what gives a home the best chance to survive a wildfire. Embers from a wildfire will find the weak link in your home's fire protection scheme and gain the upper hand because of a small, overlooked or seemingly inconsequential factor. However, there are measures you can take to safeguard your home from wildfire. While you may not be able to accomplish all the measures listed below, each will increase your home's, and possibly your family's, safety and survival during a wildfire.

ROOFS

Roofs are the most vulnerable surface where embers land because they can lodge and start a fire. Roof valleys, open ends of barrel tiles and rain gutters are all points of entry.

EAVES

Embers can gather under open eaves and ignite exposed wood or other combustible material.

VENTS

Embers can enter the attic or other concealed spaces and ignite combustible materials. Vents in eaves and cornices are particularly vulnerable, as are any unscreened vents.

WALLS

Combustible siding or other combustible or overlapping materials provide surfaces or crevices for embers to nestle and ignite.

WINDOWS and DOORS

Embers can enter gaps in doors, including garage doors. Plants or combustible storage near windows can be ignited from embers and generate heat that can break windows and/or melt combustible frames.

BALCONIES and DECKS

Embers can collect in or on combustible surfaces or the undersides of decks and balconies, ignite the material and enter the home through walls or windows.

To harden your home even further, consider protecting your homes with a residential fire sprinkler system. In addition to extinguishing a fire started by an ember that enters your home, it also protects you and your family year-round from any fire that may start in your home.

Tour a Wildfire Ready Home

Home Site and Yard: Ensure you have at least a 100-foot radius of defensible space (cleared vegetation) around your home. Note that even more clearance may be needed for homes in severe hazard areas. This means looking past what you own to determine the impact a common slope or neighbors' yard will have on your property during a wildfire.

Cut dry weeds and grass before noon when temperatures are cooler to reduce the chance of sparking a fire.

Landscape with fire-resistant plants that have a high moisture content and are low-growing.

Keep woodpiles, propane tanks and combustible materials away from your home and other structures such as garages, barns and sheds.

Ensure that trees are far away from power lines.

Roof: Your roof is the most vulnerable part of your home because it can easily catch fire from wind-blown embers. Homes with wood-shake or shingle roofs are at high risk of being destroyed during a wildfire.

Build your roof or re-roof with fire-resistant materials such as composition, metal or tile. Block any spaces between roof decking and covering to prevent ember intrusion.

Clear pine needles, leaves and other debris from your roof and gutters.

Cut any tree branches within ten feet of your roof.

Vents: Vents on homes are particularly vulnerable to flying embers.

All vent openings should be covered with ⅛-inch or smaller metal mesh. Do not use fiberglass or plastic mesh because they can melt and burn.

Attic vents in eaves or cornices should be baffled or otherwise protected to prevent ember intrusion (mesh is not enough).

Windows: Heat from a wildfire can cause windows to break even before the home ignites. This allows burning embers to enter and start internal fires. Single-paned and large windows are particularly vulnerable.

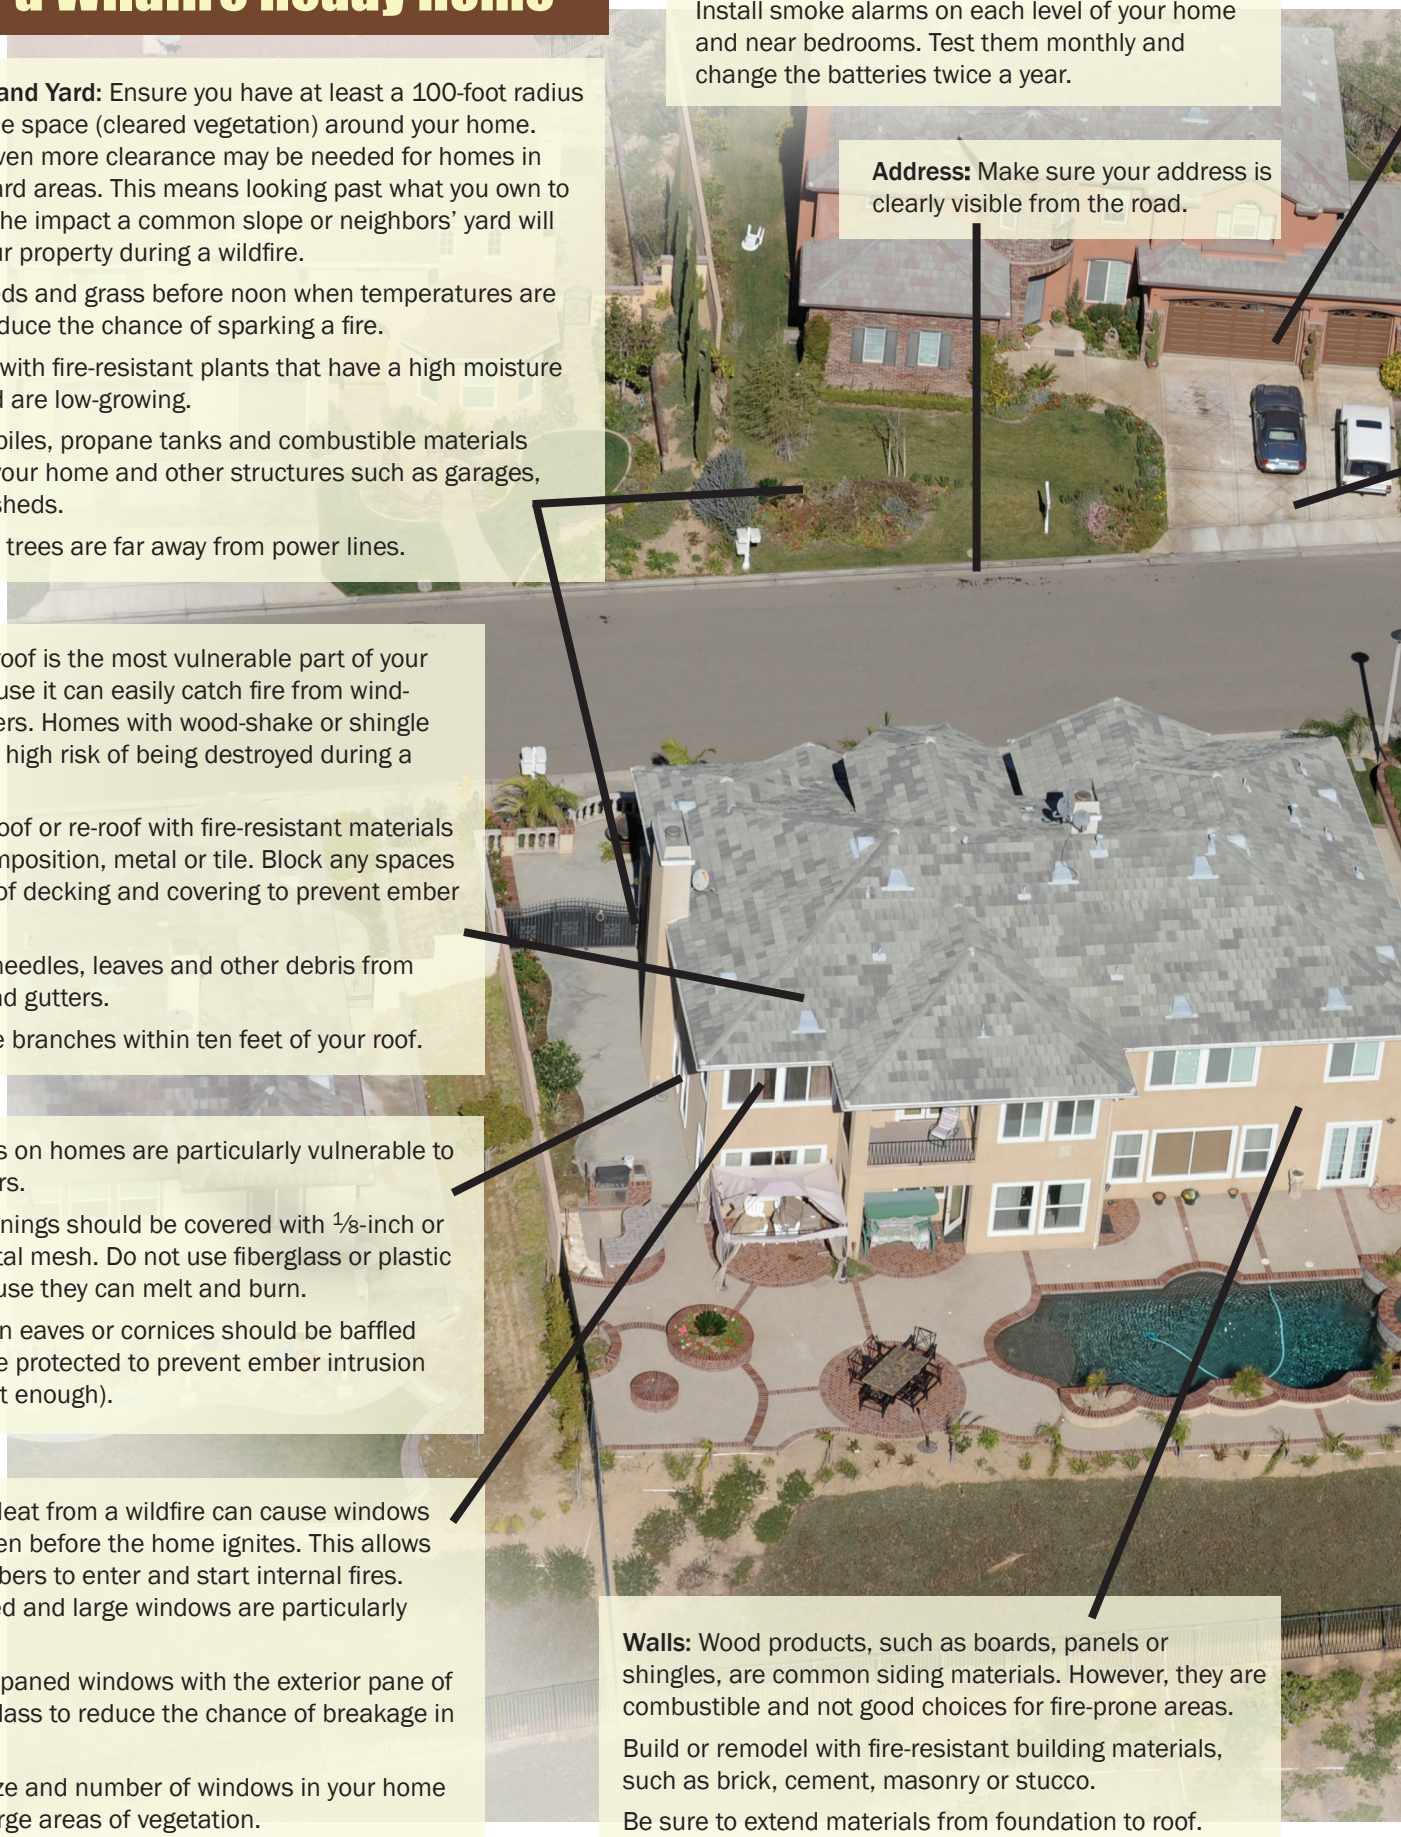
Install dual-paned windows with the exterior pane of tempered glass to reduce the chance of breakage in a fire.

Limit the size and number of windows in your home that face large areas of vegetation.

Inside: Keep working fire extinguishers on hand.

Install smoke alarms on each level of your home and near bedrooms. Test them monthly and change the batteries twice a year.

Address: Make sure your address is clearly visible from the road.



Walls: Wood products, such as boards, panels or shingles, are common siding materials. However, they are combustible and not good choices for fire-prone areas.

Build or remodel with fire-resistant building materials, such as brick, cement, masonry or stucco.

Be sure to extend materials from foundation to roof.

Garage: Have a fire extinguisher and tools such as a shovel, rake, bucket and hoe available for fire emergencies.

Install a solid door with self-closing hinges between living areas and the garage. Install weather stripping around and under door to prevent ember intrusion.

Store all combustibles and flammable liquids away from ignition sources.

Driveways and Access Roads: Driveways should be designed to allow fire and emergency vehicles and equipment to reach your house.

Access roads should have a minimum 10-foot clearance on either side of the traveled section of the roadway and should allow for two-way traffic.

Ensure that all gates open inward and are wide enough to accommodate emergency equipment.

Trim trees and shrubs overhanging the road to a minimum of 13 1⁄2 feet to allow emergency vehicles to pass.

Non-Combustible Fencing: Make sure to use non-combustible fencing to protect your home during a wildfire.

Non-Combustible Boxed In Eaves: Box in eaves with non-combustible materials to prevent accumulation of embers.

Rain gutters: Screen or enclose rain gutters to prevent accumulation of plant debris.

Water Supply: Have multiple garden hoses that are long enough to reach any area of your home and other structures on your property.

If you have a pool or well, consider a pump.

Deck/Patio Cover: Use heavy timber or non-flammable construction material for decks.

Enclose the underside of balconies and decks with fire-resistant materials to prevent embers from blowing underneath.

Keep your deck clear of combustible items, such as baskets, dried flower arrangements and other debris.

The decking surface must be ignition resistant if it's within 10 feet of the home.

Chimney: Cover your chimney and stovepipe outlets with a non-flammable screen of ¼-inch wire mesh or smaller to prevent embers from escaping and igniting a fire.

Make sure that your chimney is at least 10 feet away from any tree branches.

READY, SET, GO!

Create Your Own Wildfire Action Plan

Now that you've done everything you can to protect your house, it's time to prepare your family. Your **Wildfire Action Plan** must be prepared with all members of your household well in advance of a fire.

Use these checklists to help you prepare your Wildfire Action Plan. Each family's plan will be different, depending on their situation.

Once you finish your plan, rehearse it regularly with your family and keep it in a safe and accessible place for quick implementation.

GET READY

Prepare Your Family

- ☐ Create a **Family Disaster Plan** that includes meeting locations and communication plans and rehearse it regularly. Include in your plan the evacuation of large animals such as horses.
- ☐ Have fire extinguishers on hand and train your family how to use them.
- ☐ Ensure that your family knows where your gas, electric and water main shut-off controls are and how to use them.
- ☐ Plan several different evacuation routes.
- ☐ Designate an emergency meeting location outside the fire hazard area.
- ☐ Assemble an emergency supply kit as recommended by the American Red Cross.
- ☐ Appoint an out-of-area friend or relative as a point of contact so you can communicate with family members who have relocated.
- ☐ Maintain a list of emergency contact numbers posted near your phone and in your emergency supply kit.
- ☐ Keep an extra emergency supply kit in your car in case you can't get to your home because of fire.
- ☐ Have a portable radio or scanner so you can stay updated on the fire.

GET SET | As the Fire Approaches

- [ ] Evacuate as soon as you are set!
- [ ] Alert family and neighbors.
- [ ] Dress in appropriate clothing (i.e., clothing made from natural fibers, such as cotton, and work boots). Have goggles and a dry bandana or particle mask handy.
- [ ] Ensure that you have your emergency supply kit on hand that includes all necessary items, such as a battery powered radio, spare batteries, emergency contact numbers, and ample drinking water.
- [ ] Stay tuned to your TV or local radio stations for updates, or check the fire department website.
- [ ] Remain close to your house, drink plenty of water and keep an eye on your family and pets until you are ready to leave.

INSIDE CHECKLIST

- [ ] Shut all windows and doors, leaving them unlocked.
- [ ] Remove flammable window shades and curtains and close metal shutters.
- [ ] Remove lightweight curtains.
- [ ] Move flammable furniture to the center of the room, away from windows and doors.
- [ ] Shut off gas at the meter. Turn off pilot lights.
- [ ] Leave your lights on so firefighters can see your house under smoky conditions.
- [ ] Shut off the air conditioning.

OUTSIDE CHECKLIST

- [ ] Gather up flammable items from the exterior of the house and bring them inside (e.g., patio furniture, children's toys, door mats, etc.) or place them in your pool.
- [ ] Turn off propane tanks.
- [ ] Don't leave sprinklers on or water running - they can waste critical water pressure.
- [ ] Leave exterior lights on.
- [ ] Back your car into the driveway. Shut doors and roll up windows.
- [ ] Have a ladder available.
- [ ] Patrol your property and extinguish all small fires until you leave.
- [ ] Seal attic and ground vents with pre-cut plywood or commercial seals if time permits.

IF YOU ARE TRAPPED: SURVIVAL TIPS

- [ ] Shelter away from outside walls.
- [ ] Bring garden hoses inside house so embers don't destroy them.
- [ ] Patrol inside your home for spot fires and extinguish them.
- [ ] Wear long sleeves and long pants made of natural fibers such as cotton.
- [ ] Stay hydrated.
- [ ] Ensure you can exit the home if it catches fire (remember if it's hot inside the house, it is four to five times hotter outside).
- [ ] Fill sinks and tubs for an emergency water supply.
- [ ] Place wet towels under doors to keep smoke and embers out.
- [ ] After the fire has passed, check your roof and extinguish any fires, sparks or embers.
- [ ] Check inside the attic for hidden embers.
- [ ] Patrol your property and extinguish small fires.
- [ ] If there are fires that you can not extinguish with a small amount of water or in a short period of time, call 9-1-1.

Go! | Early!

By leaving early, you give your family the best chance of surviving a wildfire. You also help firefighters by keeping roads clear of congestion, enabling them to move more freely and do their job.

WHEN TO LEAVE

Leave early enough to avoid being caught in fire, smoke or road congestion. Don't wait to be told by authorities to leave. In an intense wildfire, they may not have time to knock on every door. If you are advised to leave, don't hesitate!

WHERE TO GO

Leave to a predetermined location (it should be a low-risk area, such as a well-prepared neighbor or relative's house, a Red Cross shelter or evacuation center, motel, etc.)

HOW TO GET THERE

Have several travel routes in case one route is blocked by the fire or by emergency vehicles and equipment. Choose an escape route away from the fire.

WHAT TO TAKE

Take your emergency supply kit containing your family and pet's necessary items.

EMERGENCY SUPPLIES

The American Red Cross recommends every family have an emergency supply kit assembled long before a wildfire or other emergency occurs. Use the checklist below to help assemble yours. For more information on emergency supplies, visit the American Red Cross Web site at www.redcross.org.

- ☐ Three-day supply of water (one gallon per person per day).
- ☐ Non-perishable food for all family members and pets (three-day supply).
- ☐ First aid kit.
- ☐ Flashlight, battery-powered radio, and extra batteries.
- ☐ An extra set of car keys, credit cards, cash or traveler's checks.
- ☐ Sanitation supplies.
- ☐ Extra eyeglasses or contact lenses.
- ☐ Important family documents and contact numbers.
- ☐ Map marked with evacuation routes.
- ☐ Prescriptions or special medications.
- ☐ Family photos and other irreplaceable items.
- ☐ Easily carried valuables.
- ☐ Personal computers (information on hard drives and disks).
- ☐ Chargers for cell phones, laptops, etc.

Note: Keep a pair of old shoes and a flashlight handy in case of a sudden evacuation at night.

Write up your Wildfire Action Plan and post it in a location where every member of your family can see it. Rehearse it with your family.

My Personal Wildfire Action Plan

During High Fire Danger days in your area, monitor your local media for information on brush fires and be ready to implement your plan. Hot, dry and windy conditions create the perfect environment for a wildfire.

VC ALERT
EMERGENCY NOTIFICATION SYSTEM

If we can't **REACH** you...
We can't **ALERT** you.

VC Alert is an emergency notification system that may be used to deliver emergency alerts when there is a threat to the health or safety of Ventura County residents.

In addition to emergency information, you may:

- ✓ Choose the location you want to be contacted about — your home, your parents' home, your workplace and your child's school.
- ✓ Receive alerts on your home phone, cellular phone, work phone, email, text messaging, facsimile or instant messaging.

For more information and to register, please visit www.vcalert.org or contact us at (805) 648-9283 or via email at vc.alert@ventura.org

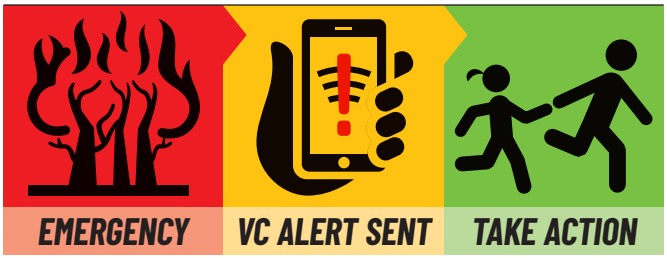
VC ALERT

EMERGENCY NOTIFICATION SYSTEM

VC Alert is an emergency notification system for Ventura County residents that may be used to alert you if there is an emergency in your community. Register your home or business address, landline, cell phone, email, and TTY device to receive emergency alerts. Alerts will be sent in both English and Spanish.

HOW IT WORKS



For more information and to register, please visit www.vcalert.org or contact us at (805) 648-9283 or via email at vc.alert@ventura.org.

Emergency Alert System

The Emergency Alert System (EAS) includes every radio and TV station as well as all cable companies in Ventura County. They are networked together to provide emergency related information in times of severe weather or other disaster.

The following are the primary local EAS stations:

KVTA 1590 AM

KHAY 100.7 FM

KMLA 103.7 FM (Spanish)

National Weather Service

HAZARD DEFINITIONS

Watch (12 to 48 hours in advance)

✓ Life and/or property threatening weather or hydrologic hazard possible. Conditions are favorable, but there is some uncertainty. Can be upgraded to a warning or advisory.

Advisory (minutes to hours in advance)

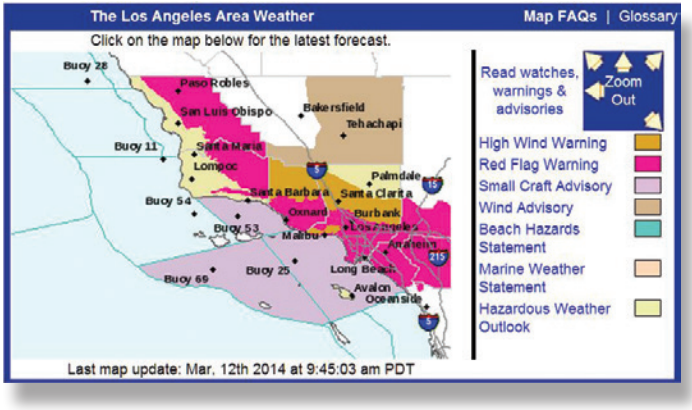
✓ Nuisance-level weather or hydrologic hazard is imminent or occurring. A non-life threatening event, but may cause problems if precautions are not taken.

Warning (minutes to hours in advance)

✓ Life and/or property threatening weather or hydrologic hazard is imminent or occurring. Take immediate action!

All warnings issued in Ventura County are rebroadcasted via the Emergency Alert System on local TV and Radio.

For more information visit National Weather Service Los Angeles/Oxnard: www.wrh.noaa.gov/lox/



Voluntary Evacuation

Proactive measures should be taken to prevent harm and to prepare personal belongings, including pets and livestock, for evacuation (i.e., Prepare to leave).

Mandatory Evacuation

An emergency poses imminent danger to life and property (i.e., Time to Leave).

Shelter-in-Place

When advised to shelter in place, follow these measures:

- ✓ Immediately go indoors.
- ✓ Shut off heaters and air conditioning.
- ✓ Seal doors and windows with duct tape and wet towels.
- ✓ If you smell the hazardous material, cover your nose and mouth with a wet cloth.
- ✓ Do not call 9-1-1 for information. Call 9-1-1 for emergencies only.
- ✓ Listen to news radio stations KVTA 1590 AM, KHAY 100.7 FM or KMLA 103.7 FM (Spanish).
- ✓ Wait for an "All Clear" notification from a news radio station, Police or Fire personnel.

You may need to survive on your own after an emergency. This means having your own food, water, and other supplies in sufficient quantity to last for at least three days. Local officials and relief workers will be on scene after a disaster, but they may not be able to reach everyone immediately. Help may arrive in a few hours or it might take days. In addition, basic services such as electricity, gas, water, sewage treatment, and telephones may be interrupted for days, weeks, or even longer.

Individuals should also consider having at least two emergency supply kits, one full kit at home and smaller portable kits in their workplace, vehicle or other places they spend time.

Recommended Items to Include in a Basic Emergency Supply Kit:

- ✓ Water, one gallon of water per person per day for at least three days, for drinking and sanitation
- ✓ Food, at least a three-day supply of non-perishable food
- ✓ Battery-powered or hand crank radio and a NOAA Weather Radio with tone alert and extra batteries for both
- ✓ Flashlight and extra batteries, or a hand crank flashlight
- ✓ First aid kit
- ✓ Whistle to signal for help
- ✓ Dust mask, to help filter contaminated air and plastic sheeting and duct tape to shelter-in-place
- ✓ Moist towelettes, garbage bags and plastic ties for personal sanitation
- ✓ Wrench or pliers to turn off utilities
- ✓ Can opener for food (if kit contains canned food)
- ✓ Local maps
- ✓ Cell phone with chargers, inverter or solar charger

Additional Items to Consider Adding to an Emergency Supply Kit:

- ✓ Prescription medications and glasses
- ✓ Infant formula and diapers
- ✓ Pet food and extra water for your pet
- ✓ Important family documents such as copies of insurance policies, identification and bank account records in a waterproof, portable container
- ✓ Cash or traveler's checks and change
- ✓ Sleeping bag or warm blanket for each person
- ✓ Complete change of clothing including a long sleeved shirt, long pants and sturdy shoes
- ✓ Household chlorine bleach and medicine dropper. When diluted nine parts water to one part bleach, bleach can be used as a disinfectant. Or in an emergency, you can use it to treat water by using 16 drops of regular household liquid bleach per gallon of water. Do not use scented, color safe or bleaches with added cleaners.
- ✓ Fire Extinguisher
- ✓ Matches in a waterproof container
- ✓ Feminine supplies and personal hygiene items
- ✓ Mess kits, paper cups, plates and plastic utensils, paper towels
- ✓ Paper and pencil
- ✓ Books, games, puzzles or other activities for children

Individuals with Disabilities or Access & Functional Needs

If you have a disability or an access and functional need, you may need to take additional steps to prepare for emergencies.

When developing an emergency supply kit, consider adding the following items:

- ✓ Durable medical equipment
- ✓ Assistive technology and extra batteries
- ✓ Food for special diets
- ✓ Prescription medicines
- ✓ Diabetic supplies
- ✓ Hearing aids and batteries
- ✓ Teletypewriter (TTY)
- ✓ Manual wheelchair
- ✓ Supplies for a service animal
- ✓ With all the advances in technology, make sure to have alternate ways of charging/maintaining your communication and assistive technology devices before disaster strikes.

www.caloes.ca.gov/Cal-OES-Divisions/Access-Functional-Needs

FAMILY EMERGENCY COMMUNICATIONS PLAN

Your family may not be together when disaster strikes, so it is important to plan in advance: how you will contact one another; how you will get back together; and what you will do in different situations.

Family Emergency Plan

- ✓ Identify an out-of town contact. It may be easier to make a long-distance phone call than to make local calls.
- ✓ Be sure every member of your family knows the phone number and has a cell phone, coins or a prepaid phone card to call the emergency contact.
- ✓ Teach family members how to use text messaging (also known as SMS or Short Message Service). Text messages can often get around network disruptions when a phone call might not be able to get through.

Planning to Stay or Go

Depending on your circumstances and the nature of the emergency, the first important decision is whether you stay where you are or to evacuate. You should understand and plan for both possibilities. You should watch TV, listen to the radio or check the Internet often for information or official instruction as it becomes available.

Emergency Plans

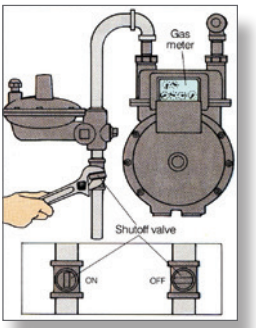
You may also want to inquire about emergency plans at places where your family spends time: work, daycare and school. If no plans exist, consider volunteering to help create one. Talk to your neighbors about how you can work together in the event of an emergency.

Learn more about the potential emergencies that could happen where you live and the appropriate way to respond to them. Knowing what to do during an emergency is an important part of being prepared and may make all the difference when seconds count.

Utilities Shut Off and Safety

NATURAL GAS

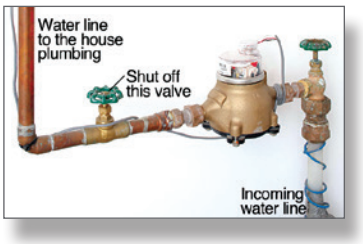
Natural gas leaks may cause explosions which are responsible for fires following disasters. It is important to know how to shut off natural gas. Because there are different gas shut-off procedures for different gas meter configurations, it is important to contact your local gas company for guidance on preparations and response regarding gas appliances and gas service to your home.



If you smell gas or hear a blowing or hissing noise, open a window and get everyone out quickly. Turn off the gas, using the outside main valve, if possible, and call the gas company from a neighbor's home.

CAUTION: If you turn off the gas for any reason, a qualified professional must turn it back on. NEVER attempt to turn the gas back on yourself.
www.socalgas.com/safety/
www.ready.gov/safety-skills

WATER



Water is a precious resource following many disasters. It is important to learn how to shut off the water at the main house valve. Before an emergency happens, locate the shut-off valve for the water line that enters your house and label this valve with a tag for easy identification. Make sure all members of your household know where it is located. Make sure this valve can be completely shut off.

Cracked lines may pollute the water supply to your house. It is wise to shut off your water until you hear from authorities that the water is safe to drink.
www.ready.gov/safety-skills

ELECTRICITY

Electrical sparks have the potential to ignite natural gas if leaking. It is wise to teach all responsible household members where and how to shut off the electricity. Locate you electrical circuit box. For your safety, always shut off all the individual circuits before shutting off the main circuit.
www.sce.com
www.ready.gov/safety-skills

Know Your Hazards

EARTHQUAKE

Before an Earthquake

1. Check for Hazards in the Home
   - ✓ Fasten shelves securely to walls.
   - ✓ Place large or heavy objects on lower shelves
2. Identify Safe Places Indoors and Outdoors
   - ✓ Under sturdy furniture such as a heavy desk or table.
   - ✓ Against an inside wall.
3. Educate Yourself and Family Members
   - ✓ Teach children how and when to call 9-1-1, Police, or Fire Department and which radio station to tune to for emergency information.
   - ✓ Teach all family members how and when to turn off gas, electricity, and water.

During an Earthquake

If indoors…

- ✓ DROP to the ground; take COVER by getting under a sturdy table or other piece of furniture; and HOLD ON until the shaking stops. If there isn't a table or desk near you, cover your face and head with your arms and crouch in an inside corner of the building.
- ✓ Stay away from glass, windows, outside doors and walls, and anything that could fall, such as lighting fixtures or furniture.
- ✓ Stay inside until the shaking stops and it is safe to go outside.

If outdoors…

- ✓ Stay there.
- ✓ Move away from buildings, streetlights, and utility wires.
- ✓ Once in the open, stay there until the shaking stops. The greatest danger exists directly outside buildings, at exits and alongside exterior walls. Ground movement during an earthquake is not the direct cause of death or injury. Most earthquake-related casualties result from collapsing walls, flying glass and falling objects.

More information on earthquakes can found at:
www.earthquakecountry.org
www.shakeout.org
www.usgs.gov

FLOOD

During A Flood

If a flood is likely in your area, you should:

- ✓ Listen to the radio or television for information.
- ✓ Be aware that flash flooding can occur. If there is any possibility of a flash flood, move immediately to higher ground. Do not wait for instructions to move.
- ✓ Be aware of streams, drainage channels, canyons and other areas known to flood suddenly. Flash floods can occur in these areas with or without such typical warnings as rain clouds or heavy rain.

✓ If you must prepare to evacuate, you should do the following:

- Secure your home. If you have time, bring in outdoor furniture. Move essential items to an upper floor.
- Turn off utilities at the main switches or valves if instructed to do so. Disconnect electrical appliances. Do not touch electrical equipment if you are wet or standing in water.

✓ If you have to leave your home, remember these evacuation tips:

- Do not walk through moving water. Six inches of moving water can make you fall. If you have to walk in water, walk where the water is not moving. Use a stick to check the firmness of the ground in front of you.
- Do not drive into flooded areas. If floodwaters rise around your car, abandon the car and move to higher ground if you can do so safely.

Driving Flood Facts:

The following are important points to remember when driving in flood conditions:

✓ Six inches of water will reach the bottom of most passenger cars causing loss of control and possible stalling.

✓ A foot of water will float many vehicles.

✓ Two feet of rushing water can carry away most vehicles including sport utility vehicles (SUV's) and pick-ups.

More information can be found at:
www.vcwatershed.net/fws/
www.vcfloodinfo.com/
www.fema.gov/national-flood-insurance-program

TERRORISM

Terrorism is defined as the use of force or violence against persons or property in violation of the criminal laws of the United States for purposes of intimidation, coercion or ransom.

Terrorists often use threats to:

- ✓ Create fear among the public.
- ✓ Try to convince citizens that their government is powerless to prevent terrorism.
- ✓ Get immediate publicity for their causes.

Acts of terrorism include: Threats of terrorism, assassinations, kidnappings, hijackings, bomb scares and bombings, cyber-attacks (computer-based), and the use of chemical, biological, nuclear and radiological weapons.

If you see something suspicious taking place then report that behavior or activity to local law enforcement or in the case of emergency call 9-1-1. Factors such as race, ethnicity, national origin or religious affiliation alone are not suspicious. For that reason, the public should report only suspicious behavior and situations (e.g., an unattended backpack in a public place or someone trying to break into a restricted area) rather than beliefs, thoughts, ideas, expressions, associations or speech unrelated to terrorism or other criminal activity. Only reports that document behavior reasonably indicative of criminal activity related to terrorism will be shared with federal partners.

TSUNAMI

Tsunamis (pronounced *soo-ná-mees*), also known as seismic sea waves (mistakenly called "tidal waves"), are a series of enormous waves created by an underwater disturbance such as an earthquake, landslide, volcanic eruption or meteorite. A tsunami can move hundreds of miles per hour in the open ocean and smash into land with waves as high as 100 feet or more.

All tsunamis are potentially dangerous, even though they may not damage every coastline they strike. A tsunami can strike anywhere along most of the U.S. coastline. The most destructive tsunamis have occurred along the coasts of California, Oregon, Washington, Alaska, and Hawaii.

The following are guidelines for what you should do if a tsunami is likely in your area:

- ✓ Turn on your radio to learn if there is a tsunami warning if an earthquake occurs and you are in a coastal area. Move inland to higher ground immediately and stay there.
- ✓ Stay away from the beach. Never go down to the beach to watch a tsunami come in. If you can see the wave you are too close to escape it.

CAUTION - If there is noticeable recession in water away from the shoreline this is nature's tsunami warning and it should be heeded. You should move away immediately.

WILDFIRES

Wildfires are now a year-round reality in Ventura County. This means that both firefighters and residents have to be on heightened alert for the threat of wildfire at all times.

Firefighters train hard and make countless preparations to be ready for a wildfire. Residents need to do the same. Successfully preparing for a wildfire requires you to take personal responsibility for protecting yourself, your family and your property.

You must do all you can to make your home resistant to wildfires and prepare your family to leave early and safely. We call this process, **"Ready, Set, Go!"**

GET READY:

- ✓ Create a Family Disaster Plan that includes meeting locations and communication plans and rehearse it regularly. Include in your plan the evacuation of large animals such as horses.
- ✓ Have fire extinguishers on hand and train your family how to use them.
- ✓ Ensure that your family knows where your gas, electric and water main shut-off controls are and how to use them.
- ✓ Plan several different evacuation routes.
- ✓ Designate an emergency meeting location outside the fire hazard area.
- ✓ Assemble an emergency supply kit, and an extra emergency supply kit in your car in case you can't get to your home because of a fire.
- ✓ Have a communication plan with emergency contact numbers of family and an out-of-area contact person.
- ✓ Have a portable radio or scanner so you can stay updated on the fire.

GET SET:

Inside Checklist:

- ✓ Shut all windows and doors, leaving them unlocked.
- ✓ Remove flammable window shades, lightweight curtains and close metal shutters.
- ✓ Move flammable furniture to the center of the room, away from windows and doors.
- ✓ Leave your lights on so firefighters can see your house under smoky conditions.
- ✓ Shut off the air conditioning.

Outside Checklist:

- ✓ Gather up flammable items from the exterior of the house and bring them inside (e.g., patio furniture, children's toys, door mats, etc.) or place them in your pool.
- ✓ Don't leave sprinklers on or water running – they can waste critical water pressure.
- ✓ Leave exterior lights on.
- ✓ Back your car into the driveway. Shut doors and roll up windows.
- ✓ Have a ladder available.
- ✓ Patrol your property and extinguish all small fires until you leave.
- ✓ Seal attic and ground vents with pre-cut plywood or commercial seals if time permits.

You Are Trapped: Survival Tips

- ✓ Shelter away from outside walls.
- ✓ Bring garden hoses inside house so embers don't destroy them.
- ✓ Patrol inside your home for spot fires and extinguish them.
- ✓ Wear long sleeves and long pants made of natural fibers such as cotton.
- ✓ Stay hydrated.
- ✓ Ensure you can exit the home if it catches fire (remember if it's hot inside the house, it is four to five times hotter outside).
- ✓ Fill sinks and tubs for an emergency water supply.
- ✓ Place wet towels under doors to keep smoke and embers out.

- ✓ After the fire has passed, check your roof and extinguish any fires, sparks or embers.
- ✓ Check inside the attic for hidden embers.
- ✓ Patrol your property and extinguish small fires.
- ✓ If there are fires that you can not extinguish with a small amount of water or in a short period of time, call 9-1-1.

GO:

By leaving early, you give your family the best chance of surviving a wildfire. You also help firefighters by keeping roads clear of congestion, enabling them to move more freely and do their job.

When To Leave

Leave early enough to avoid being caught in fire, smoke or road congestion. Don't wait to be told by authorities to leave. In an intense wildfire, they may not have time to knock on every door. If you are advised to leave, don't hesitate!

Where To Go

Leave to a predetermined location (it should be a low-risk area, such as a well-prepared neighbor or relative's house, a Red Cross shelter or evacuation center, motel, etc.)

How To Get There

Have several travel routes in case one route is blocked by the fire or by emergency vehicles and equipment. Choose an escape route away from the fire.

What To Take

Take your emergency supply kit containing your family's and pet's necessary items.

More information can be found at:
www.vcfd.org

POST-WILDFIRE DEBRIS FLOW

Debris flow and flash floods may pose a threat to homes and communities adjacent to or surrounded by wild lands in recent burn areas. Wildfires dramatically alter terrain and destroy vegetation that would normally absorb rainfall, resulting in increased risk for flood and debris flows. Debris flows develop when unabsorbed water picks up soil, sediment, boulders and other debris and are carried in a stream of floodwaters. Areas affected by wildfire remain at risk until vegetation is restored, which may take up to 5 years or longer during drought periods.

Reduce Your Risk of Debris Flow Hazard

- ✓ Do not build near steep slopes, mountain edges, near or below drainage ways, or natural erosion areas.
- ✓ Consider a geologic hazard assessment of your property that includes a site visit by a professional geologist.
- ✓ Consult your insurance agent and visit FloodSmart.gov for information on flood insurance.
- ✓ Plant drought and fire-resistant ground cover on slopes.
- ✓ Build retaining walls that account for upslope drainage.
- ✓ In debris flow prone areas, build channels or walls to direct the flow around buildings.
- ✓ Stay informed of the weather including potential rainfall amounts and intensities.

Recognize the Warning Signs

- ✓ Prolonged periods of heavy rainfall and strong wind gusts.
- ✓ Unusual sounds, such as trees cracking or a faint rumbling that intensifies.
- ✓ Changes that occur in the hillside landscape, such as patterns of arcuate cracks or soil exposure, bulging at the bottom of the slope, leaning trees, bare soil areas, water drainage from bottom of slope.
- ✓ Flowing or falling mud or debris may precede larger flows.
- ✓ Water breaks through the ground surface in new locations.
- ✓ Fences, retaining walls, utility poles, or trees fall.
- ✓ Report warning signs of debris flow to 911.

Increase Your Chance for Survival

- ✓ Stay tuned to NOAA weather reports via radio or television, and visit https://www.vcwatershed.net/fws/gmap.html to see real-time rainfall intensity levels.
- ✓ Evacuate for the duration and a few hours after the storm. Avoidance is your best protection.
- ✓ Proceed with caution while driving in high-risk areas.

If a Debris Flow Impacts Your Property

- ✓ Return home only when officials have declared the area safe.
- ✓ Have the home inspected for structural damage before re-entering.
- ✓ Keep power and gas off until a licensed professional has inspected your systems for safety.
- ✓ Discard food items that have been contaminated by floodwater or debris.
- ✓ Boil water for drinking and food preparation until authorities declare your water supply is safe.
- ✓ Prevent mold by removing wet contents immediately.
- ✓ Beware of wild animals or poisonous snakes that may have been swept into the area.
- ✓ Seek advice from a technical expert for evaluating potential future hazards or designing corrective techniques.

Want to get involved in your local community?

American Red Cross
www.redcross.org/ca/ventura
As the world's leading humanitarian organization, their network of volunteers have responded to disasters, provided lifesaving education, helped families to prepare for emergencies before they occur, and kept members of our Armed Forces connected with their loved ones during times of tragedy and joy.

Auxiliary Communication Services (ACS)
www.vc-acs.org/
Licensed Radio Amateurs use a wide range of radio bands, each one with its particular strength in overcoming the barriers to radio communications. Amateur Radio operators can also use a wide range of communication modes, whether TV, data, voice, or Morse code to exchange messages.

Community Emergency Response Teams (CERT)
http://vcfd.org/CERT
Phone: (805) 987-1514
Ventura County Fire Department in coordination with FEMA (Federal Emergency Management Agency) have joined together to assist residents with disaster preparedness education and training. Following a major disaster, first responders who provide fire and medical services will not be able to meet the demand for service. The local population will have to rely on each other for help in order to meet their immediate life-saving and life sustaining needs. The Community Emergency Response Team is a program that focuses on that preparedness. CERT teams within each community are to be prepared, self-activated, independently organized and neighborhood oriented with support from cities and public safety agencies.

Disaster Assistance Response Team (DART) – Camarillo
https://www.cityofcamarillo.org/Police/DART.pdf
Disaster Assistance Response Team (DART) – Thousand Oaks
https://todart.org/
DART members are trained in: Basic Life Support, First Aid, CPR, Urban Search and Rescue, Incident Command System (ICS), Media Relations at the Incident, Traffic and Crowd Control, Fire Suppression, Scene Survey and Damage Assessment; and Mass Casualty Management and Triage.

Simi Valley Disaster Service Worker Team
www.simivalley.org/index.aspx?page=269
The Simi Valley Disaster Service Work Team's mission is to minimize the loss of life, suffering and damage to property following disasters by training and utilizing highly motivated community members in preparedness, response and recovery activities.

Emergency Volunteer Rescue Team (EVRT)
http://www.vcas.us/
Emergency Volunteer Rescue Team (EVRT) members assist Ventura County Department of Animal Services during times of disasters such as wildland fires, flooding, earthquakes or any emergency incident requiring the evacuation of livestock.

Medical Reserve Corps
http://www.vchca.org/ventura-county-medical-reserve-corps
Develop partnerships to educate, train and deploy citizen volunteers, including health care professionals (active and retired), in case of a large-scale local emergency.

National Weather Service
https://www.wrh.noaa.gov/lox/spotter/becomeaspotter.php
Anyone can become a Weather Spotter for the National Weather Service. All it takes is an hour or two of training. Our local spotter program leader conducts training sessions often throughout the area. You also now have the option of becoming certified through an online course.

United Way / Volunteer Ventura County
http://www.volunteerventuracounty.org/
Today's United Way focuses on addressing the underlying causes of community issues and why problems exist. United Way supports programs that are not just 'stop gap' measures, but ultimately preventative ones that create real and lasting change by improving peoples' lives. Social issues are not limited to any one particular city or to one kind of family, they are everywhere. That's why United Way works throughout Ventura County to help build stronger communities.

READY VENTURA COUNTY
ABOUT US

The Ventura County Sheriff's Office of Emergency Services in partnership with FEMA and the Ad Council localized the federal Ready campaign to assist Ventura County residents in preparing for, responding to and recovering from a local emergency or disaster within our community. Developed in 2011, Ready Ventura County aims to get the public involved and ultimately increase the level of basic preparedness throughout Ventura County. The Ready Ventura County message remains consistent with the national campaign: **Get a Kit. Make a Plan. Be Informed. Get Involved.**

1 Introduction

This memorandum describes the potential wildfire impacts that may result from the construction and operation of the Ventura Ranch Farmworker Housing Project (Project). The information presented is based on a review of existing resources and applicable laws, regulations, guidelines, and standards, as well as the Fire Protection Plan (FPP) and the Wildfire Evacuation Study (WES) prepared for the Project. Publicly available sources were reviewed in the development of this memorandum, including, but not limited to, the CAL FIRE Fire and Resource Assessment Program (FRAP) database, the County of Ventura General Plan, Ventura County Municipal Code, and Ventura County Local Hazard Mitigation Plan, and the updated Ventura County Initial Study Assessment Guidelines (ISAGs). Section 1.1 describes the existing environment, including vegetation and fuels, climate, topography, fire hazard severity zone designation, fire history, and emergency response and fire protection. Section 2 provides an overview of the regulatory setting related to wildfire and presents laws, ordinances, regulations, and standards (LORS) applicable to wildfire. Section 3 identifies potential environmental impacts that may result from Project construction, operation, and maintenance, assessed based on the CEQA Appendix G thresholds and the Ventura County ISAGs. Section 4 provides references used to develop this memorandum.

1.1 Project Location

The project site is located at 4884 N Ventura Avenue in the unincorporated Ventura County, north of the city of Ventura. It is directly south of the Norway Tract, also known as the Valley Vista community. The proposed housing development will consist of three parcels of 6.11 acres, 4.81 acres and 8.66 acres. A 63.34-acre parcel will be created that will remain undeveloped open space and will be designated a Conservation Subdivision lot. That lot will be owned by a Conservation Entity.

The existing on-site land use of the proposed development is currently vacant agricultural land and a single family dwelling with some outbuildings. Surrounding land uses include a residential community to the north, agricultural open space to the east and south and Ventura Avenue, Ojai Freeway and vacant land to the west.

1.2 Project Description

The proposed Ventura Ranch Project is a comprehensive residential community exclusively for farmworkers and their families, located north of the city of Ventura. The community will consist of 328 apartments, along with community spaces such as two indoor community centers, a teen/adult recreational amenity (such as a basketball court), play fields, community garden, walking paths, and playgrounds, within an unincorporated area of the County of Ventura. This community will provide critical farmworker housing for Ventura County. In recent years, affordable, safe farmworker housing has been increasingly difficult to find in the county, hindering growth of the local agricultural industry and burdening local farmers and farmworkers.[1]

The project will be developed in three phases as detailed on the Conceptual Site Plan and Tentative Parcel Map. Phase One will consist of a total of 92 units, Phase Two will consist of 104 units and Phase Three will consist of 132 units. Each of the three phases will be owned by a separate limited partnership.

[1] Project Summary, Jensen Design & Survey, 2025

The project site is located at 4884 N Ventura Avenue in the unincorporated Ventura County, north of the city of Ventura. It is directly south of the Norway Tract, also known as the Valley Vista community. Two driveways will provide access in and out of the site onto Ventura Avenue. An emergency access only, gated road will connect the project to the Valley Vista community to the north through the extension of Floral Drive. This access will only be available in the event of an emergency.[2]

[2] Ibid

2 Existing Conditions

2.1 Fire Hazard Severity Zone Designation

CAL FIRE's Fire and Resource Assessment Program (FRAP) database includes map data documenting areas of significant fire hazards in the state. These maps categorize geographic areas of the state into different fire hazard severity zones (FHSZs). The FHSZ maps identify Moderate, High, and Very High FHSZs within State Responsibility Areas (SRA) and Local Responsibility Areas (LRA). CAL FIRE uses FHSZs to classify anticipated fire-related hazards. Fire hazard severity classifications take into account vegetation, topography, weather, crown fire production, and ember production and movement.

As shown in Figure 2, Fire Hazard Severity Zone Map, of the FPP, the Project site lies within an area considered a Very High Fire Hazard Severity Zone (VHFHSZ) within the LRA as designated by CAL FIRE and the Ventura County Fire Protection District (also referred to as Ventura County Fire Department (VCFD)) (CAL FIRE 2025). The VHFHSZ designation can be attributed to a variety of factors including highly flammable, dense, drought-adapted desert chaparral vegetation, annual grasslands, seasonal strong winds, and a Mediterranean climate that results in vegetation drying during the months most likely to experience Santa Ana winds.

2.2 Vegetation and Land Cover

Vegetation on site is comprised of ruderal forbs and cut stalks from past agricultural uses. There are no active agricultural practices currently taking place on site.

The vegetation characteristics described above are used to model fire behavior, discussed in Sections 3.2 and 3.3 of the FPP. Variations in vegetative cover type and species composition have a direct effect on fire behavior. Some plant communities and their associated plant species have increased flammability based on plant physiology (resin content), biological function (flowering, retention of dead plant material), physical structure (bark thickness, leaf size, branching patterns), and overall fuel loading. For example, non-native grass dominated plant communities become seasonally prone to ignition and produce lower intensity, higher spread rate fires. In comparison, California sagebrush scrub can produce higher heat intensity and higher flame lengths under strong, dry wind patterns, but does not typically ignite or spread as quickly as light, flashy grass fuels.

2.3 Climate, Weather and Wind Patterns

The project area has daily highs in the summer and early fall months (June–October) exceeding 73°F. Precipitation typically occurs between October and April with average rainfall of 14 inches, per year (Weather Spark 2025).

The project site, like much of Southern California, is influenced by prevailing wind patterns. Prevailing winds are winds that blow from a single direction over a specific area of the Earth. The prevailing wind pattern is from the west (on-shore), but the presence of the Pacific Ocean causes a diurnal wind pattern known as the land/sea breeze system. The highest wind velocities are associated with downslope, canyon, and Santa Ana winds. The project site is subject to seasonally strong winds, such as Santa Ana winds, which can result in periodic extreme fire weather conditions that occur throughout Ventura County.

The average hourly wind speed in Ventura experiences significant seasonal variation over the course of the year.

The windier part of the year lasts for 7.3 months, from October 25 to June 3, with average wind speeds of more than 6.1 miles per hour. The windiest month of the year in Ventura is December, with an average hourly wind speed of 7.6 miles per hour (Weather Spark 2025).

Typically, the highest fire danger is produced by the high-pressure systems that occur in the Great Basin, which result in the Santa Ana winds of Southern California. Sustained wind speeds during recent major fires in Ventura County reached up to 60 mph during extreme conditions, as was the case during the most recent wildfires in Ventura County, such as the Mountain Fire (VC Star 2024). The Santa Ana wind conditions are a reversal of the prevailing southwesterly winds that usually occur on a region-wide basis during late summer and early fall. Santa Ana winds are warm winds that flow from the higher desert elevations in the north through the mountain passes and canyons. As they converge through the canyons, their velocities increase. Consequently, peak velocities are highest at the mouths of canyons and dissipate as they spread across valley floors. Santa Ana winds generally coincide with the regional drought period and the period of highest fire danger.

2.4 Topography

Topography influences fire risk by affecting fire spread rates. Typically, steep terrain results in faster fire spread up slope and slower spread down slope. Terrain that forms a funneling effect—such as chimneys, chutes, or saddles—on the landscape can result in especially intense fire behavior, including faster spread and higher intensity. Conversely, flat terrain tends to have little effect on fire spread, resulting in fires that are driven by vegetation and wind.

Topography of the proposed project consists primarily of flat terrain with a slight gradient to the west. Elevations within the project site range from about 200 to 250 feet above mean sea level (AMSL). East of the project site (open space parcels) the topography includes steeper slopes ranging from 250 to 700 feet AMSL, which may serve to funnel or channel winds, thus increasing their velocity and potential for influencing wildfire behavior.

2.5 Fire History

Fire history data provides valuable information regarding fire spread, fire frequency, most vulnerable areas, and significant ignition sources, amongst others. In turn, this understanding of why fires occur in an area and how they typically spread can then be used for pre-planning and designing defensible communities.

CAL FIRE's Fire and Resource Assessment Program (FRAP) database summarizes fire perimeter data dating to the late 1800s, but which is incomplete due to the fact that it only includes fires over 10 acres in size and has incomplete perimeter data, especially for the first half of the 20th century (Syphard and Keeley 2016). However, the data does provide a summary of recorded fires and can be used to show whether large fires have occurred in the Project area, which indicates whether they may be possible in the future.

According to available data from the CAL FIRE FRAP database[3], 67 fires have burned in the vicinity of the project site since the beginning of the historical fire data record. Recorded wildfires within 5 miles range from one (1) acre to 281,791 acres (2017 Thomas Fire) and the average fire size is 6,672 acres (2,503 when not including the

[3] Based on polygon GIS data from CAL FIRE's FRAP, which includes data from CAL FIRE, USDA Forest Service Region 5, BLM, NPS, Contract Counties and other agencies. The data set is a comprehensive fire perimeter GIS layer for public and private lands throughout the state and covers fires 10 acres and greater between 1878–2023.

Thomas Fire). Only one fire has burned on the project site – the 2017 Thomas Fire – which burned about 0.02 acres in the southeast corner (CAL FIRE FRAP 2025). Fire history for the general vicinity of the project site is illustrated in the map in Appendix B (Project Vicinity Fire History Map) of the FPP.

Based on an analysis of the CAL FIRE FRAP fire history data set, specifically the years in which the fires burned, the average interval between wildfires in the area (includes areas up to roughly five miles from the Project site) was calculated to be 1.6 years with intervals ranging between zero and 14 years. Based on this analysis, it is expected that wildfire that could impact the Project may occur, if weather conditions coincide, roughly every two years with the realistic possibility of shorter or longer interval occurrences, as observed in the fire history records.

2.6 Emergency Response and Fire Protection

The VCFD jurisdiction covers approximately 848 square miles in size and has an estimated population of 840,000. VCFD responds to fires, medical emergencies, traffic accidents, land and water rescues, hazardous materials calls, environmental hazards, and a variety of public service requests. VCFD provides emergency and non-emergency services to all unincorporated areas in Ventura County along with the cities of Ojai, Port Hueneme, Moorpark, Camarillo, Santa Paula, Simi Valley, and Thousand Oaks. (VCFD 2025).

The VCFD currently operates 34 Fire Stations. The nearest fire stations to the project site are Stations 22 and 23, which are located approximately 5.0 and 8.7 miles from the project site, respectively. Primary response would be from Station 23, with Station 22 responding as necessary. Fire Station 23 houses five firefighters who staff Medic Engine 23, staffed by three personnel, and Rescue 23, staffed by two personnel. Fire Station 22 houses three firefighters who cross-staff Engine 22, Brush Engine 322, and Utility 22.[4] Mutual aid, automatic aid and other agreements with surrounding fire departments enable VCFD to provide the fastest and highest level of service.[5] Ventura City Fire Station 1 may be available to respond to the Project site as a mutual aid resource, and is located approximately 3.1 miles from the project site. This station houses three firefighters who staff a paramedic engine.[6]

INTENTIONALLY LEFT BLANKINTENTIONALLY LEFT BLANK

3 Laws, Ordinances, Regulations, and Standards

This section discusses federal, state, and regional environmental regulations, plans, and standards related to wildfire that may be applicable to the Proposed Project.

3.1 Federal

National Fire Protection Association (NFPA) Codes, Standards, Practices, and Guides

National Fire Protection Association (NFPA) codes, standards, recommended practices, and guides are developed through a consensus standards development process approved by the American National Standards Institute. This process brings together professionals representing varied viewpoints and interests to achieve consensus on fire and other safety issues. NFPA standards are recommended guidelines and nationally accepted good practices in fire protection, but are not laws or codes unless adopted as such or referenced as such by the California Fire Code or the local fire agency.

NFPA 10, Standard for Portable Fire Extinguishers (2018): A long-standing standard, which specifies the types, sizes, rating, and locations for portable fire extinguishers. It also provides information on how to calculate the number and size of portable fire extinguishers needed.

NFPA 11, Standard for Low-, Medium-, and High-Expansion Foam (2024): NFPA 11 is a longstanding standard, which provides recommendations for design and installation of firefighting foam systems and portable equipment. It also provides recommendations regarding calculating the amount of foam concentrate and solution needed on a flammable or combustible liquid fire.

NFPA 13, Standard for Installation of Sprinkler Systems (2022): NFPA 13 is the standard for design and installation of automatic fire sprinkler systems in a building. It provides the requirements for the type of system needed in a particular occupancy, water supply, sprinkler head flow and pressures, the locations of sprinkler heads, and installation of the system. This standard is referenced by the California Fire Code.

NFPA 22, Standard for Water Tanks for Private Fire Protection (2018): Provides recommendations for the design, construction, installation, and maintenance of tanks and accessory equipment that supply water for private fire protection.

NFPA 30, Flammable and Combustible Liquids Code (2021): This standard provides safeguards to reduce the hazards associated with the storage, use, and handling of flammable and combustible liquids. It provides detailed information regarding tank storage, spacing, dispensing of liquids, portable containers, and other related operations. NFPA 30 is referenced by the California Fire Code.

NFPA 70, National Electrical Code (2020): NFPA 70 is the standard for the design, installation, and inspection of electrical hazards. It includes recommendations for various types of occupancies and also provides recommendations and criteria for the location and installation of “explosion proof” electrical systems.

NFPA 72, National Fire Alarm and Signaling Code (2022): NFPA 72 is the standard for the design, installation, and operation of fire alarm systems in various occupancies. This standard is used by fire alarm system designers when designing and installing a system. It is utilized also by fire agencies when reviewing plans for new systems.

Federal Wildland Fire Management Policy

The Federal Wildland Fire Management Policy was developed in 1995, updated in 2001, and again in 2009 by the National Wildfire Coordinating Group, a federal multi-agency group that establishes consistent and coordinated fire management policy across multiple federal jurisdictions. An important component of the Federal Wildland Fire Management Policy is the acknowledgement of the essential role of fire in maintaining natural ecosystems. The Federal Wildland Fire Management Policy and its implementation are founded on the following guiding principles, found in the Guidance for Implementation of Federal Wildland Fire Management Policy (National Wildfire Coordinating Group 2009):

- Firefighter and public safety is the first priority in every fire management activity.
- The role of wildland fire as an essential ecological process and natural change agent will be incorporated into the planning process.
- Fire management plans, programs, and activities support land and resource management plans and their implementation.
- Sound risk management is a foundation for all fire management activities.
- Fire management programs and activities are economically viable, based upon values to be protected, costs, and land and resource management objectives.
- Fire management plans and activities are based upon the best available science.
- Fire management plans and activities incorporate public health and environmental quality considerations.
- Federal, state, tribal, local, interagency, and international coordination and cooperation are essential.
- Standardization of policies and procedures among federal agencies is an ongoing objective.

National Fire Plan

The National Fire Plan, officially titled Managing the Impacts of Wildfire on Communities and the Environment: A Report to the President In Response to the Wildfires of 2000, was a presidential directive in 2000 as a response to severe wildland fires that had burned throughout the United States. The National Fire Plan focuses on reducing fire impacts on rural communities and providing assurance for sufficient firefighting capacity in the future. The plan addresses five key points: Firefighting, Rehabilitation, Hazardous Fuels Reduction, Community Assistance, and Accountability. The plan continues to provide invaluable technical, financial, and resource guidance and support for wildland fire management across the United States. The U.S. Forest Service and the Department of the Interior are working to successfully implement the key points outlined in the plan (DOI/USDA 2000).

International Fire Code

Created by the International Code Council, the International Fire Code (IFC) addresses a wide array of conditions hazardous to life and property, including fire, explosions, and hazardous materials handling or usage (although not a federal regulation, but rather the product of the International Code Council). The IFC places an emphasis on prescriptive and performance-based approaches to fire prevention and fire protection systems. Updated every 3

years, the IFC uses a hazards classification system to determine the appropriate measures to be incorporated to protect life and property (often times these measures include construction standards and specialized equipment). The IFC uses a permit system (based on hazard classification) to ensure that required measures are instituted (International Code Council 2017).

International Wildland–Urban Interface Code

The International Wildland–Urban Interface Code is published by the International Code and is a model code addressing wildfire issues.

3.2 State

California Government Code

California Government Code Sections 51175 through 51189 provide guidance for classifying lands in California as fire hazard areas and requirements for management of property within those lands. CAL FIRE is responsible for classifying FHSZs based on statewide criteria, and makes the information available for public review. Further, local agencies must designate, by ordinance, Very High FHSZs within their jurisdiction based on the recommendations of CAL FIRE.

Section 51182 sets forth requirements for maintaining property within fire hazard areas, such as defensible space, vegetative fuels management, building materials and standards. Defensible space consisting of 100 feet of fuel modification on each side of a structure, but not beyond the property line unless findings conclude that the clearing is necessary to significantly reduce the risk of structure ignition in the event of a wildfire. Clearance on adjacent property shall only be conducted following written consent by the adjacent owner. Further, trees must be trimmed from within 10 feet of the outlet of a chimney or stovepipe, vegetation near buildings must be maintained, and roofs of structures must be cleared of vegetative materials. Exemptions may apply for buildings with an exterior constructed entirely of nonflammable materials.

California Code of Regulations

Title 14 Natural Resources

Title 14, Division 1.5, Chapter 7, Subchapter 3, Fire Hazard, also sets forth requirements for defensible space if the distances specified above cannot be met. For example, options that have similar practical effects include noncombustible block walls or fences, 5 feet of noncombustible material horizontally around the structure, installing hardscape landscaping or reducing exposed windows on the side of the structure with a less-than-30-foot setback, or additional structure hardening such as those required in the California Building Code (CBC), California Code of Regulations Title 24, Part 2, Chapter 7A.

Title 24 California Building Standards Code

California Building Code

Part 2 of Title 24 contains the California Building Code (CBC). Chapter 7A of the CBC regulates to building materials, systems, and/or assemblies used in the exterior design and construction of new buildings located within a wildland–urban interface fire area. The purpose of this Chapter is to establish minimum standards for the protection of life

and property by increasing the ability of a building located in any FHSZ within a State Responsibility Area or a wildland–urban interface fire area to resist the intrusion of flames or burning embers projected by a vegetation fire, and to contribute to a systematic reduction in conflagration losses. New buildings located in such areas must comply with the ignition-resistant construction standards outlined in CBC Chapter 7A.

The VHFHSZ designation on the Project site would require buildings to implement ignition-resistive construction and provide up to 200-feet of defensible space (treated, maintained vegetation) between structures and open space areas. Since the entire Proposed Project site is classified as VHFHSZ, the requirements of Chapter 7A of the 2019 California Building Code (CBC), or then current edition, would apply to all project buildings.

California Fire Code

Part 9 of Title 24 contains the California Fire Code (CFC), which incorporates by adoption the International Fire Code with necessary California amendments. The purpose of this code is to establish the minimum requirements to safeguard the public health, safety, and general welfare from the hazards of fire, explosion, or dangerous conditions in new and existing buildings, structures, and premises, and to provide safety and assistance to firefighters and emergency responders during emergency operations. Chapter 49 of the CFC contains minimum standards for development in the wildland–urban interface and fire hazard areas.

The CFC and Office of the State Fire Marshal provide regulations and guidance for local agencies in the development and enforcement of fire safety standards. The CFC is updated and published every 3 years by the California Building Standards Commission.

California Public Resources Code

California Public Resource Code Section 4290 requires minimum fire safety standards related to defensible space that are applicable to residential, commercial and industrial building construction in State Responsibility Area lands and lands classified and designated as Very High FHSZs. These regulations include road standards for fire apparatus access, standards for signs identifying roads and buildings, fuel breaks and green belts, and minimum water supply requirements. It should be noted that these regulations do not supersede local regulations which equal or exceed minimum regulations required by the state.

Public Resource Code Section 4291 requires a reduction of fire hazards around buildings located adjacent to a mountainous area, forest-covered lands, brush-covered lands, grass-covered lands or land that is covered in flammable material. It is required to maintain a minimum 100 feet of vegetation management around all buildings and is the primary mechanism for conducting fire prevention activities on private property within CAL FIRE jurisdiction. Further, PRC 4291 requires the removal of dead or dying vegetative materials from the roof of a structure, and trees and shrubs must be trimmed from within 10 feet of the outlet of a chimney or stovepipe. Exemptions may apply for buildings with an exterior constructed entirely of nonflammable materials.

California Department of Forestry and Fire Protection (CAL FIRE)

CAL FIRE is tasked with reducing wildfire-related impacts and enhancing California's resources. CAL FIRE responds to all types of emergencies including wildland fires and residential/commercial structure fires. In addition, CAL FIRE is responsible for the protection of approximately 31 million acres of private land within the state and, at the local level, is responsible for inspecting defensible space around private residences. CAL FIRE is responsible for enforcing State of California fire safety codes included in the CCR and California Public Resources Codes. Public Resources

Code 4291 states generally that any person operating any structure located on brush-covered lands or land covered with flammable material is required to maintain defensible space around the structure. CCR Title 14 Section 1254 identifies minimum clearance requirements required around utility poles. In SRAs within the jurisdiction of CAL FIRE, the Fire Safety Inspection Program is an important tool for community outreach and enforcement of state fire codes.

CAL FIRE also inspects utility facilities and makes recommendations regarding improvements in facility design and infrastructure. Joint inspections of facilities by CAL FIRE and the utility owner are recommended by CAL FIRE so that each entity may assess the current state of the facility and the successfully implement fire prevention techniques and policies. Violations of state fire codes discovered during inspections are required to be brought into compliance with the established codes. If a CAL FIRE investigation reveals that a wildfire occurred as a result of a violation of a law or negligence, the responsible party could face criminal and/or misdemeanor charges. In cases where a violation of a law or negligence has occurred, CAL FIRE has established the Civil Cost Recovery Program, which requires parties liable for wildfires to pay for wildfire-related damages.

Fire Hazard Severity Zone Mapping

As previously discussed, CAL FIRE's FRAP database provides data documenting areas of significant fire hazards throughout the state, based on fuel loading, slope, fire history, weather, and other relevant factors as directed by Public Resources Code Sections 4201–4204 and Government Code Sections 51175–51189. FHSZs are ranked from Moderate to Very High, and are categorized for fire protection within a Federal Responsibility Area, State Responsibility Area, or Local Responsibility Area under the jurisdiction of a federal agency, CAL FIRE, or local agency, respectively. As noted above and depicted in Figure 2, Fire Hazard Severity Zone Map, of the FPP, the project site and surrounding area is located within a Very High FHSZ.

California Strategic Fire Plan

The 2018 Strategic Fire Plan for California reflects CAL FIRE's focus on (1) fire prevention and suppression activities to protect lives, property, and ecosystem services, and (2) natural resource management to maintain the state's forests as a resilient carbon sink to meet California's climate change goals and to serve as important habitat for adaptation and mitigation. The Strategic Fire Plan for California provides a vision for a natural environment that is more fire resilient; buildings and infrastructure that are more fire resistant; and a society that is more aware of and responsive to the benefits and threats of wildland fire; all achieved through local, state, federal, tribal, and private partnerships (CAL FIRE 2018). Plan goals include the following:

1. Identify and evaluate wildland fire hazards and recognize life, property and natural resource assets at risk, including watershed, habitat, social and other values of functioning ecosystems. Facilitate the collaborative development and sharing of all analyses and data collection across all ownerships for consistency in type and kind.
2. Promote and support local land use planning processes as they relate to: (a) protection of life, property, and natural resources from risks associated with wildland fire, and (b) individual landowner objectives and responsibilities.
3. Support and participate in the collaborative development and implementation of local, county and regional plans that address fire protection and landowner objectives.
4. Increase fire prevention awareness, knowledge and actions implemented by individuals and communities to reduce human loss, property damage and impacts to natural resources from wildland fires.
5. Integrate fire and fuels management practices with landowner/land manager priorities across jurisdictions.

6. Determine the level of resources necessary to effectively identify, plan and implement fire prevention using adaptive management strategies.
7. Determine the level of fire suppression resources necessary to protect the values and assets at risk identified during planning processes.
8. Implement post-fire assessments and programs for the protection of life, property, and natural resource recovery.

Mutual Aid Agreements

The California Disaster and Civil Defense Master Mutual Aid Agreement, as provided by the California Emergency Services Act, provides statewide mutual aid between and among local jurisdictions and the state. The statewide mutual aid system exists to ensure that adequate resources, facilities, and other supports are provided to jurisdictions whenever resources prove to be inadequate for a given situation. Each jurisdiction controls its own personnel and facilities but can give and receive help whenever needed. The VCFD participates in these mutual aid, automatic aid and other agreements with surrounding fire departments. In some instances the closest available resource may come from another fire department.

3.3 Local

The proposed project would be subject to state and federal agency planning documents described above, as well as the regional or local planning documents as summarized below.

Ventura County 2040 General Plan

Hazards and Safety Element

The Ventura County 2040 General Plan was adopted by the Ventura County Board of Supervisors in 2020, along with the Program Environmental Impact Report (PEIR) for the Ventura County 2040 General Plan. Chapter 7 of the General Plan is the Hazards and Safety Element, which addresses wildfire as one of the hazards faced by the County. This section focuses on protecting against and preparing for potential wildfire hazards as well as restoration efforts for previously burned areas. The following goals and policies from the Ventura County 2040 General Plan Hazards and Safety Element that apply to wildfire hazards and may be applicable the project are as follows.

Goals

HAZ-1: To improve the resilience of the County to wildfire risk by locating, designing, and constructing development in a manner that minimizes the risk, and by providing effective fire prevention, suppression, and rescue services and facilities.

Policies

HAZ-1.1: Fire Prevention Design and Practices. The County shall continue to require development to incorporate design measures that enhance fire protection in areas of high fire risk. This shall include but is not limited to incorporation of fire-resistant structural design, use of fire-resistant landscaping, and fuel modification around the perimeter of structures.

HAZ-1.2: Defensible Space Clear Zones. The County shall require adherence to defensible space standards, or vegetation "clear zones," for all existing and new structures in areas that are designated as Hazardous Fire Areas by the Ventura County Fire Protection District and High Fire Hazard Severity Zones by the California Department of Forestry and Fire Protection.

HAZ-1.4: Development in High Fire Hazard Severity Zones and Hazardous Fire Areas. The County shall require the recordation of a Notice of Fire Hazard with the County Recorder for all new discretionary entitlements (including subdivisions and land use permits) within areas designated as Hazardous Fire Areas by the Ventura County Fire Department or High Fire Hazard Severity Zones by the California Department of Forestry and Fire Protection (CAL FIRE).

HAZ-1.5: Discouragement of Home-Building in Very High Fire Severity Zones. The County should discourage the building of homes in Very High Fire Severity Zones.

HAZ-1.6: Wildfire Risk Education. The County shall continue to develop and distribute educational materials and conduct educational outreach activities informing the public about wildfire risk and protection strategies.

Goals

HAZ-12: To provide for the safe and efficient evacuation of residents in times of need.

Policies

HAZ-12.1: Access Points for New Subdivisions. The County shall require new residential subdivisions to provide not less than two means of access for emergency vehicles and resident evacuation. A deviation from this policy is only allowed if a single proposed access road conforms to the County Road Standards, Ventura County Fire Department Access Standards, and when the County Fire Chief approves the proposed deviation.

Ventura County Municipal Code

2022 Ventura County Building Code: 2022 California Building Code as adopted with amendments.

2022 Ventura County Fire Code: 2022 California Fire Code as adopted with amendments.

Ventura County Fire Department Guidelines: guidelines regarding fuel modification zones, defensible space, landscaping, fire protection plans, and other related topics (410, 412, 416, 418, 420, 423, 424, 515).

Ventura County Multi-Jurisdictional Local Hazard Mitigation Plan

The purpose of the County's Multi-Jurisdictional Hazard Mitigation Plan (Ventura County 2022) is to identify the County's hazards, review and assess past disaster occurrences, estimate the probability of future occurrences, and set goals to mitigate potential risks to reduce or eliminate long-term risk to people and property from natural and human-made hazards.

Ventura County Emergency Operations Plan

The 2021 Ventura County Operational Area (OA) Emergency Operations Plan (EOP) describes a comprehensive emergency management system that provides for a planned response to disaster situations associated with natural disasters, technological incidents, terrorism, and nuclear-related incidents. This plan delineates operational concepts relating to various emergency situations, identify components of the Emergency Management Organization, and describes the overall responsibilities for protecting life and property and providing for the overall well-being of the population. The plan also identifies the sources of outside support that might be provided (through mutual aid and specific statutory authorities) by other jurisdictions, state and federal agencies, and the private sector.

County of Ventura All Hazards Evacuation Plan

The 2024 All Hazards Evacuation Plan details the County of Ventura's responsibilities for the management of an evacuation response. This plan was created as an annex to the Ventura County Operational Area EOP. This plan can be used in conjunction with the EOP and other annexes and plans designed for the protection of the population. Responsibilities, tasks, and pertinent activities pertaining to a large-scale evacuation within the County are defined. The plan is consistent with SEMS and the Incident Command System, while also integrating local plans, ordinances, and laws.

4 Technical Analysis Summary

4.1 Fire Protection Plan

A Fire Protection Plan (FPP) (Dudek 2025) has been prepared for the proposed Project. The FPP assesses the potential wildland fire hazards and identifies the measures necessary to reduce wildfire risks. Additionally, the FPP memorializes the fire safety requirements of the Fire Authority Having Jurisdiction (FAHJ), namely the Ventura County Fire Department (VCFD). Requirements are based on site-specific characteristics, applicable code requirements, and incorporate input from the proposed Project's applicant, project planners, engineers, and architects, as well as VCFD.

The FPP considers the property location, topography, surrounding combustible vegetation (fuel types), climatic conditions, and fire history. The plan addresses water supply, access, structural ignitability and fire resistive building features, fire protection systems and equipment, impacts to existing emergency services, defensible space, and vegetation management.

The FPP included a field site assessment, a review of the project site characteristics and fire environment, an analysis of anticipated fire behavior using BehavePlus modeling program (Andrews, Bevins, and Seli 2008), an assessment of emergency response capabilities, and a review of fire safety requirements and Project compliance. The results of these analyses are summarized below. Refer to the FPP for full details.

4.1.1 Results

Anticipated Fire Behavior

Dudek utilized BehavePlus modeling program (Andrews, Bevins, and Seli 2008) to analyze potential fire behavior on and adjacent to the Project site, with assumptions made for the pre- and post-Project slope and fuel conditions. The analysis evaluates fire behavior variables to objectively predict flame lengths, intensities, and spread rates for five modeling scenarios. These fire scenarios incorporated observed fuel types representing the dominant on-site and off-site vegetation on adjacent land to the east, south and west, in addition to slope gradients, and wind and fuel moisture values for both the 50th percentile weather (summer, on-shore winds) and the 97th percentile weather (fall, off-shore winds). Modeling scenario locations were selected to better understand different fire behavior that may be experienced on or adjacent to the Project site. Locations of modeling run (fire scenarios) is presented graphically in Figure 4, Wildfire Behavior Modeling Scenarios, of the FPP. The results of fire behavior modeling analysis for existing and post-Project conditions are presented in Tables 1 and 2, respectively.

Existing Condition

As presented in Table 1, a worst-case fire (Scenario 1) under gusty Santa Ana winds and low fuel moistures is expected to be fast moving modeled at advancing 4.7 mph from east to west. Flame length values were modeled at 20 feet in untreated native grass on lands adjacent to the property. Ember spotting is projected to occur up to 1.2 miles from the flaming front.

Table 1. Fire Behavior Results for Existing Conditions

Fire Scenarios	Spread Rate (mph)	Fireline Intensity (BTU/ft/sec)	Flame Length (ft)	Spotting Distance[1] (mi)
Scenario 1: 30% slope, 40 mph wind from NE				
Fuel Model GR4 – grassland	4.7	3840	20.0	1.2
Fuel Model GR1 – treated grassland	0.3	37	2.4	0.3
Scenario 2: 30% slope, 40 mph wind from NE				
Fuel Model GS2 – coastal sage shrub	2.3	1899	14.5	1.0
Fuel Model FM8 – avocado orchard	0.1	46	2.6	0.3
Scenario 3: 30% slopes, 40 mph wind from NE				
Fuel Model SH2 – coastal sage scrub/chaparral	0.8	1728	13.9	0.9
Fuel Model FM8 – avocado orchard	0.1	46	2.6	0.3
Scenario 4: 5% slope, 20 mph wind from S				
Fuel Model GR2 – fallow agricultural field	0.9	360	6.8	0.3
Fuel Model GR1 – harvested agricultural field	0.3	37	2.4	0.2
Scenario 5: 10% slope, 20 mph wind from SW				
Fuel Model NB1 – paved street	0	0	0	0
Fuel Model GR4 – grassland	1.8	1450	12.8	0.5
Fuel Model TL6 – eucalyptus windrow	0.2	189	5.0	0.3

Note:
[1] Spotting distance from a wind driven surface fire.

Post-Project Condition

As presented in Table 2, Fire Behavior Results for Post-Project Conditions, Dudek conducted modeling of the Project site for post-development fuel conditions. The fuel modification area includes paved roadways, parking lots and irrigated landscaping throughout the proposed Project. Wildfire conditions improve under all scenarios when fuel modification zones are created and maintained. Scenario 2, the worst-case scenario under post-Project conditions, would result in a wildfire advancing 1.6 mph with 9.4-foot flame lengths in maintained shrubs with ember spotting to a distance of 0.7 miles from the front of the fire.

The fuel modification areas within the Project site experienced a significant reduction in flame length and wildfire intensity. Post-Project fuel modification results in flame lengths that are less than half of the existing conditions for Scenarios 1, 2, and 3 where the wildfire is approaching from the north and east. Post-Project ember spotting for Scenarios 1, 2, and 3 has been reduced by half as compared to existing conditions. Anticipated fire behavior is significantly improved with Post-Project fuel modification for a Scenario 4 wildfire approaching from the southwest. Flame lengths are reduced to less than one-third of those produced by existing conditions while ember spotting is reduced by half.

Table 2. Fire Behavior Results for Post-Project Conditions

Scenario	Spread Rate (mph)	Fireline Intensity (BTU/ft/sec)	Flame Length (ft)	Spotting Distance[1] (mi)
Scenario 1: 30% slope, 40 mph wind from NE				
Fuel Model GR1 – maintained grassland for fuel modification	0.3	37	2.4	0.3
Scenario 2: 30% slope, 40 mph wind from NE				
Fuel Model GS1 – maintained shrubs for fuel modification	1.6	745	9.4	0.7
Fuel Model 8 – avocado	0.1	46	2.6	0.3
Scenario 3: 30% slope, 40 mph winds from NE				
Fuel Model SH1 – maintained shrubs for fuel modification	1.0	569	8.3	0.6
Fuel Model NB1 – paved roadway	0	0	0	0
Fuel Model 8 – Irrigated land-scaping	0.1	46	2.6	0.3
Scenario 4: 5% slope, 20 mph wind from S				
Fuel Model NB1 – paved roadway	0	0	0	0
Fuel Model 8 – Irrigated land-scaping	0.1	26	2.0	0.2
Scenario 5: 5% slope, 20 mph wind from SW				
Fuel Model NB1 – paved roadway	0	0	0	0
Fuel Model GR4 – grassland	1.8	1450	12.8	0.5
Fuel Model 8 – Irrigated land-scaping	0.1	26	2.0	0.2

Note:
[1] Spotting distance from a wind driven surface fire.

Fire Safety Requirements

The FPP demonstrates that the proposed Project would comply with all applicable portions of the Ventura County Building and Fire Codes, as amended and in effect at the time of the report's preparation. The proposed Project also complies with the California Code of Regulations Titles 14 and 24, Chapter 7A of the 2022 California Building Code (CBC) (or then current edition). The proposed Project would also be subject to the provisions of section 4291 of the Public Resources Code regarding brush clearance standards around structures and the related Ventura County Fire Department Guidelines. The FPP details these requirements and fire protection features.

Emergency Response

The project is within the jurisdiction of VCFD. The VCFD currently operates 34 Fire Stations, two of which are analyzed in the FPP due to their proximity to the Proposed Project site and could respond to an incident at the Project site (Stations 22 and 23). Primary response would be from Station 23, with Station 22 responding as necessary. Mutual aid, automatic aid and other agreements with surrounding fire departments enable VCFD to provide the

fastest and highest level of service.[7] Ventura City Fire Station 1 may be available to respond to the Project site as a mutual aid resource.

Table 3 (Fire Department Responding Stations Summary) presents a summary of the location, fire apparatus equipment, staffing levels, maximum travel distance, and estimated travel time for the stations that may respond to a fire or medical emergency at the Project site.

Based on the Proposed Project site location in relation to existing VCFD stations, travel time to the site for the first responding engine from Station 23 is approximately 9.2 minutes to the main project entrance. Travel to the furthest occupied point of the development may require an additional 30-60 seconds to navigate the quarter-mile distance that includes two roundabouts. A secondary response from Station 22 would arrive in just over 15 minutes. Ventura City Station 1 would arrive in just under 6 minutes.

The VCFD has a response time goal of 8.5 minutes for Suburban areas 90% of the time and 12 minutes for Rural areas 90% of the time.[8] The Project is located in a rural area. With an anticipated travel time of 9.2 minutes for the nearest VCFD fire engine and 2.48 minutes for call processing and turnout time, the total expected response time to the Project is 11.68 minutes, which is within the VCFD response time goal for a facility in a rural location.

Table 3. Fire Department Responding Stations Summary

Station	Location	Equipment	Staffing	Maximum Travel Distance	Travel Time**
Station 23	15 Kunkle St., Oak View, California	▪ (1) Paramedic Engine Co. ▪ (1) Rescue	On-Duty: 5	5.0 mi.*	9.2 minutes*
Station 22	466 S. La Luna Ave., Ojai, California	▪ (1) Engine Co. ▪ (1) Brush Engine ▪ (1) Utility	On-Duty: 3	8.7 mi.*	15.4 minutes*
Ventura City Station 1	717 N. Ventura Ave. Ventura, California 93001	▪ (1) Paramedic Engine Co.	On duty: 3	3.1 mi.*	5.9 minutes*

Notes:
* Distance measured to entrance of the proposed VRFH Project site at 4884 N. Ventura Ave.
** Assumes travel to the project entrance, and application of the ISO formula, T=0.65+1.7(Distance), a 35 mph travel speed, and does not include turnout time.

Demand for Service

The Project is estimated to generate 49 calls for service to the VCFD per year at build out and full occupancy, which is a 0.1% increase in call volume when compared to the total calls for service in 2023. Most of the calls for service are expected to be medical-related calls, consistent with typical emergency call statistics.

Service level requirements are not expected to be significantly impacted by the Project. VCFD's busiest stations, which do not have additional responses from a Battalion Chief, average 12.5 calls per day. Station 23 averaged

7 Ventura County Fire Department. https://vcfd.org/emergency-response/
8 Ventura County Fire Department. Public records request response, May 19, 2025.

nearly 3 calls per day and Station 22 averaged nearly 4 calls per day.[9] An additional 49 calls for service per year equates to nearly 1 call per week. It is anticipated that most of the calls for service from the Project area will be handled by Medic Engine 23 and Rescue 23 responding from Station 23. The Project will not significantly increase the average daily call volume for Station 23.

4.1.2 FPP Recommendations

The fire protection measures are evaluated to provide at least equivalent protection based on the experience of the preparers of this report.

1. Construct all buildings in accordance with CBC Chapter 7A building code requirements.
2. Maintain two ingress/egress points on North Ventura Avenue and an emergency vehicle access (EVA) connection to Floral Drive in the Norway Tract / Valley Vista community to the north.
3. Install Fuel Modification Zones (FMZs) consisting of Zone 0, Zone 1, and Zone 2 fuel modification and vegetation management around the buildings and in the common areas of the Project (see Fuel Modification Plan).
4. Conduct FMZ inspections annually, performed by VCFD, the property manager, or a mutually agreed upon 3rd party to their satisfaction. This measure will ensure that the FMZs are functioning as intended.
5. Prepare a Construction Site Safety Plan and Fire Department Site Access Plan for each phase of development.
6. The Project developer, or successor owner, will retain ownership of the property as a rental community, with complete control and responsibility for all maintenance.

4.2 Wildfire Evacuation Study

A Wildfire Evacuation Study (WES) was prepared for the project based on guidance from and is consistent with Ventura County Operational Area (OA) EOP (2021), the Ventura County All Hazards Evacuation Plan (2024), and the City's Emergency Operations Plan (EOP) (2021). The WES summarizes the applicable regulations, standards, and planning tools related to evacuation, the local and regional evacuation planning procedures and operations, and discusses the anticipated types of evacuations at the Project site, evacuation procedures, the evacuation road network, and the potential for evacuation-related impacts.

The WES includes an evacuation model analysis performed by Dudek Traffic Engineers for the Project to determine how long it would take for occupants of the Project and the other land uses in the study area (see Figure 4, Evacuation Areas and Evacuation Routes, in the WES) to evacuate to nearby urban areas and/or freeways in case of a fire emergency. This analysis was performed in accordance with the requirements of the County OA EOP – Annex, All Hazards Evacuation Plan (September 2024) for the calculation of evacuation times. The evacuation modeling analysis used the traffic simulation software PTV Vissim. Three evacuation scenarios were modeled: Scenario 1 – Existing Conditions, Scenario 2 – Ventura Rant Farmworker Housing (Project) Only, and Scenario 3 – Existing plus Project Conditions. All scenarios assume a mass evacuation event in which all vehicles leave the study simultaneously. Background traffic is not considered in this analysis, populations outside of the study area are not assumed

[9] Ventura County Fire Department. Total Responses per VCFD Station, 2023-2024.

to be included in the same evacuation order as the proposed project and would not be assumed to add vehicles to the roadway network during the evacuation event.

The evacuation routes used in the analysis are shown in Figure 4 of the WES. The major transportation corridor within the study area is SR-33. Ventura Avenue and Crooked Palm Road will serve as the primary evacuation routes out of the study area. The main Project driveways to Ventura Avenue will serve as the primary evacuation routes for the Project's residential land uses. Ventura Avenue provides access to Canada Larga Road and Shell Road West which allows entry to SR-33.

4.2.1 Results

Table 4, Evacuation Modeling Scenarios and Evacuation Time Summary, summarizes the evacuation time for each analysis scenario. The evacuation time does not depict the evacuation time for each individual person within an evacuation area, but rather the total amount of time needed to evacuate all populations modeled from an area. Populations located in closer proximity to the IC designated safe zone will safely evacuate sooner than the total calculated evacuation time identified in Table 3. Detailed evacuation travel time analysis information is provided in Appendix A, Evacuation Modeling Technical Memorandum.

As shown below, in Table 4, the following is a summary of the evacuation time for each scenario:

- Scenario 1: It would take approximately 43 minutes to evacuate the existing land uses.
- Scenario 2: It would take approximately 37 minutes to evacuate the proposed Project.
- Scenario 3: It would take approximately 58 minutes to evacuate the existing land uses and cumulative projects.

Table 4. Evacuation Modeling Scenarios and Evacuation Time Summary

Scenario	Total Evacuation Vehicles			Evacuation Time (Minutes) by Area		Maximum Evacuation Time by Scenario (H:MM)	Average Evacuation Time by Scenario (H:MM)
	Existing Areas	Ventura Ranch Farmworker Housing Project Area	Total	Existing Areas	Ventura Ranch Farm-worker Housing Project Area		
1: Existing 2025	1,095	0	1,095	43.91	0.00	0:43	0:40
2: Project Only	0	565	565	0.00	37.98	0:37	0:37
3: Existing plus Project	1,095	565	1,660	53.53	58.55	0:58	0:53

Notes: 00.00 = Maximum evacuation time for each scenario (time for last vehicle to leave the network and enter a safe area)

4.2.2 WES Recommendations

The WES recommends a proactive approach to evacuation outreach and education, including the "Ready, Set, Go!" program. Ventura Ranch Farmworker Housing Project can identify a Fire Safety Coordinator that is responsible for:

1. Overseeing implementation of this WES and overall fire coordination with VCFD and VCSO.

2. Implementing a proactive facility wildfire education program utilizing a multi-pronged approach to fire safety following the "**Ready, Set, Go!**" approach to wildfire evacuation, to include, but not limited to:
    a. Annual wildfire and evacuation safety awareness meeting in coordination with local fire agencies.
    b. Annual reminder notices will be provided to each employee encouraging them to review this WES and be familiar with evacuation protocols.
    c. The Project website will host a webpage dedicated to wildfire and evacuation education and awareness, which should include a copy of this Wildfire Evacuation Study and the resources provided herein.
3. Coordinating an annual fire evacuation drill/ fire exercise to ensure proper safety measures have been implemented, facility awareness and preparation of a facility-wide **Ready, Set, Go!**" plan.
4. Organizing an employee training and awareness through various practices:
    a. New hire fire awareness and evacuation training
    b. Ongoing staff training
    c. Facility sweeps by trained staff
    d. Strategically placed fire safety and evacuation/sheltering protocol information, as determined by the Fire Safety Coordinator.

While the practices above for would support an informed populace and would further improve safety and reduce and/or avoid problems during an evacuation, the evacuation modeling herein is not predicated on implementation of those practices. Therefore, as previously demonstrated, the Project would not expose people or structures to a significant risk of loss, injury or death involving wildland fires or substantially impair implementation of or physically interfere with an adopted emergency evacuation plan or emergency response plan.

INTENTIONALLY LEFT BLANK

5 Impacts Analysis

The Project is being considered for a CEQA exemption under Section 15183 for consistency with the Ventura County 2040 General Plan (County of Ventura 2020a). Therefore, the following impacts analysis assesses whether the project would result in new or more significant impacts related to wildfire than were previously analyzed in the previously certified Program EIR for the Ventura County General Plan (PEIR) (County of Ventura 2020b). The following analysis assesses whether the Project would have Project-specific effects that were not analyzed in the prior PEIR, or that cannot be mitigated by existing policies.

The previously approved PEIR analyzes wildfire impacts in Section 4.9 Hazards, Hazardous Materials, and Wildfire with the following threshold:

- Impact 4.9-6: Expose People to Risk of Wildfire by Locating Development in a High Fire Hazard Area/Fire Hazard Severity Zone or Substantially Impairing an Adopted Emergency Response Plan or Evacuation Plan or Exacerbate Wildfire Risk

The PEIR finds that implementation of the 2040 General Plan would expose people or structures to a significant risk of loss, injury, or death involving wildland fires, and exacerbate wildfire risk, because it would accommodate future development in or adjacent to high and very high FHSZs or Hazardous Fire Areas, and wildfire impacts would be **significant and unavoidable** with the following rationale (County of Ventura 2020b):

> The County has adopted the MHMP, which identifies mitigation strategies to minimize fire hazard risks, has adopted the EOP that provides guidance for handling large-scale emergencies, discourages development in fire hazard areas, and requires development to implement a variety of best management practices and design standards to ensure development is fire resistant. Nevertheless, future development would be allowed to occur at the urban-wildland interface, to increase access, human activity, and infrastructure in undeveloped areas of the county occurs and could result in the exacerbation of the potential for wildfires to occur. While Policy HAZ-12.2 requires periodic updates of emergency plans, there may be a gap between new development and plan update. Because implementation of the 2040 General Plan could result in development that exacerbates the potential for wildfires to occur and the resulting adverse environmental effects that are associated with these events, this impact would be **potentially significant**.

Mitigation Measures

The County has adopted and implemented programs to minimize wildfire risks including the MHMP. In addition, the Ventura County CWPP reduces hazardous fuels throughout the County and provide measures to reduce structural ignitability in at-risk communities. The Fire Hazard Reduction Program requires mandatory 100-feet of brush clearance around structures located in or adjacent to Hazardous Fire Areas. Many communities also have adopted their own emergency response plans. The 2040 General Plan includes a suite of policies and implementation programs that address a full spectrum of wildfire prevention standards for new development including vegetation management, fire suppression equipment, discouraging development in fire hazard areas, and education programs to prevent wildfires. Finally, existing federal and State building code standards, including the recently-adopted 2019 fire code, would require future development to be designed to minimize

fire risk. Because the effects of a wildfire are not limited to development within high FHSZs but can easily spread to adjacent communities, any development in or adjacent to a designated FHSZs or near wildland areas is at risk for wildfire. While compliance with federal, State, and local requirements would limit risk, this risk cannot be completely eliminated. No other additional policies or programs are available that could eliminate the potential for wildfires or their environmental effects to occur because the only way to fully mitigate additional exposure of people to wildfire or exacerbation of wildfire risk is to prohibit all development in or near any areas that are at risk for wildfire. Based on the topography and vegetation characteristics of the county, very few if any such areas exist. Further, many existing developed areas already pose a wildfire risk because of their proximity to wildland areas. The County has undertaken a substantial effort to implement policies and implementation programs that would protect people and structures from the risk of wildfires while at the same time promoting the economic growth of the County. No additional feasible policies or implementation programs are available to reduce the risk of wildfire exposure, exacerbation, or resulting adverse environmental effects to less than significant.

Significance after Mitigation

This impact would be significant and unavoidable.

Although the PEIR finds that wildfire impacts would be significant and unavoidable, it is important to distinguish that this analysis was conducted at a programmatic scale, and project-specific fire safety features and design features that could reduce potential impacts were not available at the time of preparation of the PEIR. A project-level analysis allows for review of these project-specific features that may aid in reducing potential impacts, as further discussed in the analysis that follows.

5.1 Thresholds of Significance

The significance criteria used to evaluate the proposed project's impacts related to wildfire are based on Ventura County's draft updated Initial Study Assessment Guidelines (ISAGs) (Ventura County 2025). The initial draft of the updated ISAGs was first released for public review from April 24 – May 24, 2025. Revisions were made in response to the public comments received on the initial draft and additional reviews conducted by County staff. The revised draft is dated July 2025 and it includes markups to identify changes from the April 2025 draft. According to updated ISAGs, projects should be evaluated using the following thresholds of significance:

WIL-1 If located in or adjacent to an HFA, a project may have a significant impact if it would exacerbate wildfire risks due to slope, prevailing winds, and other factors, and thereby expose project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire.

WIL-2 If located in or adjacent to an HFA, a project may have a significant impact if it would expose people or structures to a significant risk of loss, injury, or death involving wildfire, including downslope or downstream flooding or landslides as a result of runoff, post-fire slope instability, or drainage changes.

WIL-3 If located in or adjacent to an HFA, a project may have a significant impact if it would require the installation or maintenance of infrastructure to accommodate the project (such as roads, fuel breaks, emergency water sources, power lines, or other utilities) that may exacerbate fire risk or that may result in substantial temporary or ongoing impacts to the environment.

WIL-4 If located in or adjacent to an HFA, a project may have a significant impact if it would substantially impair or obstruct implementation of the Ventura County Emergency Operations Plan.

WIL-5 If located in or adjacent to an HFA, a project may have a significant impact if it would substantially impair or obstruct primary or alternative evacuation routes.

For purposes of the Ventura County Fire Code, areas classified as a HFA are designated as a Wildland urban interface area. A wildland-urban interface (WUI) is defined in the Ventura County Fire Code, as may be amended, which states: a geographical area identified by the state as a FHSZ in accordance with the Public Resources Code Sections 4201 through 4204 and Government Code Sections 51175 through 51189, or other areas designated by the Ventura County Fire Protection District to be at a significant risk from wildfires, including HFAs (County of Ventura 2025). As discussed in section 2.1, the project site is located in an area designated as a Very High FHSZ. As such, the project site is also designated as a HFA and WUI area.

5.2 Impacts Analysis

Impact WIL-1 If located in or adjacent to an HFA, a project may have a significant impact if it would exacerbate wildfire risks due to slope, prevailing winds, and other factors, and thereby expose project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire.

The project proposes to develop a residential community consisting of 328 one-, two- and three-bedroom apartments and community amenities. The project will be developed in three phases as detailed on the Conceptual Site Plan and Tentative Parcel Map. Phase One will consist of a total of 92 units, Phase Two will consist of 104 units, and Phase Three will consist of 132 units. Development of the Project would introduce new populations, habitable structures, human activity, roads, and associated infrastructure into a LRA Very High FHSZ. Slopes on the project site are relatively flat, however adjacent open space to the east includes steeper slopes which may serve to funnel or channel winds, thus increasing their velocity and potential for influencing wildfire behavior. Prevailing winds in the project area are from the west (on-shore), however, the project site is subject to seasonally strong winds, such as Santa Ana winds, which can result in periodic extreme fire weather conditions that occur throughout Ventura County. Given the Project location in a fire prone area, wildfire is likely to occur in the region, which could expose project occupants to risks associated with wildfire.

As with development proposed under the General Plan and analyzed in the PEIR, the project would comply with all regulations and requirements for development in a Very High FHSZ or HFA. The VCFD Fire Code and 2022 CFC and 2022 CBC (adopted by reference with several modifications) governs the building, infrastructure, and defensible space requirements for the Project. The proposed Project would comply with all applicable portions of the Ventura County Building and Fire Codes, as amended and in effect at the time of this report's preparation (California Fire Code Adopted). The proposed Project also complies with the California Code of Regulations Titles 14 and 24, Chapter 7A of the 2022 California Building Code (CBC) (or then current edition). Chapter 7A of the CBC addresses reducing ember penetration into homes, a leading cause of structure loss from wildfires (California Building Standards Commission 2019). Updated fire codes now focus on mitigating former structural vulnerabilities through construction techniques and materials so that the buildings are resistant to ignitions from direct flames, heat, and embers, as indicated in the 2022 California Building Code (Chapter 7A, Section 701A Scope, Purpose, and Application) (California Building Standards Commission 2019).

The proposed Project would also be subject to the provisions of section 4291 of the Public Resources Code regarding brush clearance standards around structures and the related Ventura County Fire Department Guidelines. The Project would include 100 feet or more of Fuel Modification Zone (FMZ), which consists of asphalt roadways and parking stalls, and a fully irrigated landscape. The conceptual FMZ map is presented in Figure 5 (Fuel Modification Plan) of the FPP. Vegetation management will also be implemented as an interim FMZ throughout the construction phases for each structure as there may be a period where the development is exposed to wildland fuels. FMZs will be implemented according to the VCFD requirements for the entire Project. As demonstrated by the fire behavior analysis in the FPP, and summarized above in Section 4.1, Project FMZs would result in a significant reduction in flame length and wildfire intensity.

The Project would implement all recommendations provided by the FPP including:

1. Construct all buildings in accordance with CBC Chapter 7A building code requirements.
2. Maintain two ingress/egress points on North Ventura Avenue and an emergency vehicle access (EVA) connection to Floral Drive in the Norway Tract / Valley Vista community to the north.
3. Install Fuel Modification Zones (FMZs) consisting of Zone 0, Zone 1, and Zone 2 fuel modification and vegetation management around the buildings and in the common areas of the Project (see Fuel Modification Plan).
4. Conduct FMZ inspections annually, performed by VCFD, the property manager, or a mutually agreed upon 3rd party to their satisfaction. This measure will ensure that the FMZs are functioning as intended.
5. Prepare a Construction Site Safety Plan and Fire Department Site Access Plan for each phase of development.
6. The Project developer, or successor owner, will retain ownership of the property as a rental community, with complete control and responsibility for all maintenance.

Additionally, the project has been reviewed by the VCFD for consistency with local policies. The VCFD requires projects located in a Very High Fire Hazard Severity Zone to have two points of access that are separated by a minimum of 1,000 feet. In lieu of providing the minimum separation, VCFD requires an additional 100 feet of vegetation fuel modification for a total of 200 feet. Based on the Project's site plan, the Project site achieves 100 feet or more of FMZ, which consists of asphalt roadways and parking stalls, and a fully irrigated landscape. However, the project has less than 1,000 feet of separation between the two primary points of access for the Project. As a condition of approval, an additional 100 feet of FMZ will be provided as an additional fire protection measure, and a total of 200 feet of FMZ will provided as discussed below.

A typical landscape/fuel modification installation consists of a 100-foot-wide fuel management zone from each structure extending outward towards undeveloped areas. The Project would provide 200 feet of vegetation fuel modification and management, per VCFD requirements. The proposed FMZ would occur around the perimeter of the Project and would be 200 feet extending outward from buildings. All highly flammable native vegetation shall be removed or thinned in accordance with VCFD Standard 515. The landscaped areas of the FMZ will be planted with drought-tolerant, fire-resistant vegetation. The Project's plant palette will be approved by the VCFD. A permanent, automatic irrigation system will be installed within the irrigated portions of the FMZ to maintain hydrated plants. The interior landscaped areas of the Project will meet FMZ standards. Additional details regarding the FMZ standards and conceptual FMZ are described in Section 5.4.2.1 and 5.4.2.2 of the FPP.

Although the Project would introduce new potential ignition sources and introduce a new community with permanent on-site occupants into a fire prone area, and project occupants could be exposed to pollutants generated by

wildfire, the uncontrolled spread of wildfire, and exposed to direct or indirect risk of wildfire due in part to natural hillside/slope conditions, prevailing winds, and natural vegetation in a fire prone area, The Project design features, asphalt roads and parking stalls, fully irrigated landscaping, and defensible space up to 200 feet from structures provides a reasonable level of safety for the Project..

As concluded in the PEIR, compliance with federal, State, and local requirements would reduce risk, however this risk cannot be completely eliminated. The project would be consistent with the General Plan PEIR, General Plan policies, as demonstrated by the FPP and WES prepared for the project, and project-specific design features and fire safety measures would aid in reducing the risk. There are no site-specific conditions or impacts peculiar to the project related to wildfire that were not addressed in the PEIR. . Therefore, the project would not result in impacts that are more severe than found in the previously certified PEIR.

Impact WIL-2 If located in or adjacent to an HFA, a project may have a significant impact if it would expose people or structures to a significant risk of loss, injury, or death involving wildfire, including downslope or downstream flooding or landslides as a result of runoff, post-fire slope instability, or drainage changes.

The Project site is relatively flat, however, surrounding areas have steeper slopes. The United States Geologic Survey Landslide Hazards Program indicate the Project site and surrounding slopes to the east are susceptible to landslides (USGS 2025). Vegetation plays a vital role in maintaining existing drainage patterns and the stability of soils. Plant roots stabilize the soil, and leaves, stems and branches intercept and slow water, allowing it to more effectively percolate into the soil. Removal of surface vegetation reduces the ability of the soil surface to absorb rainwater and can allow for increased runoff that may include large amounts of debris or mud-flows. If hydrophobic conditions exist post-fire, the rate of surface water runoff is increased as water percolation into the soil is reduced. The potential for surface runoff and debris flows therefore increases for areas recently burned by large wildfires (Moench and Fusaro 2012). As previously discussed, multiple wildfires have burned within a 5-mile radius of the Project site, according to available data from the CAL FIRE in the FRAP database, and one fire has burned on the project site – the 2017 Thomas Fire – which burned about 0.02 acres in the southeast corner of the Project site. However, based on site observations, vegetation has rebounded since the 2017 fire, resulting in stabilization of soils from post-fire conditions. As such, conditions associated with post-fire slope instability are not present on site or in immediately surrounding areas. Nonetheless, the location in a fire prone area with landslide susceptibility could result in exposure of people or structures to the risk of downslope or downstream flooding or landslides as a result of runoff, post-fire slope instability, or drainage changes.

The project would be required to be developed in accordance with a construction general permit and geotechnical recommendations, including grading, building orientation, slope maintenance, cut and fill slope design, which are all designed to ensure that slope stability is maintained. All future structures would be designed and set back from the bottom of slopes in accordance with applicable building codes. Adherence to the existing regulatory requirements, the Project would not substantially alter the existing drainage pattern or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off site. The project would be consistent with the General Plan PEIR, General Plan policies, as demonstrated by the FPP and WES prepared for the project, and project-specific design features and fire safety measures would aid in reducing the risk. There are no site-specific conditions or impacts peculiar to the project related to drainage patterns, runoff, on flooding that we re not addressed in the PEIR. Impacts would not be more severe than the previously certified PEIR.

Impact WIL-3 If located in or adjacent to an HFA, a project may have a significant impact if it would require the installation or maintenance of infrastructure to accommodate the project (such as roads, fuel breaks, emergency water sources, power lines, or other utilities) that may exacerbate fire risk or that may result in substantial temporary or ongoing impacts to the environment.

Development of the Project would require the installation and maintenance of associated infrastructure, including roads, utilities, and fuel modification zones. Given that the activities involved with installation or maintenance of associated infrastructure would require ground disturbance and the use of heavy machinery associated with trenching, grading, site work, and other construction and maintenance activities, the installation of related infrastructure could potentially result in new sources of ignition, or temporary or ongoing impacts to the environment. However, construction activities associated with installation and maintenance of associated infrastructure would be subject to regulations for construction in a fire hazard area, as well as recommendations and requirements stipulated in the FPP.

As discussed on the FPP, vegetation management requirements shall be implemented at commencement and throughout the construction phase. Vegetation management shall be performed pursuant to the FAHJ on all building locations prior to the start of work and prior to any import of combustible construction materials. Adequate fuel breaks shall be created around all grading, site work, and other construction activities in areas where there is flammable vegetation. The FPP also sets for that prior to bringing lumber or combustible materials onto the Project site, site improvements within the active development area shall be in place, including utilities, operable fire hydrants, an approved, temporary roadway surface, and fuel modification zones established. These features will be approved by the fire department or their designee prior to combustibles being brought on-site. Further, the FPP recommends preparation of a Construction Site Safety Plan and Fire Department Site Access Plan for each phase of development. The Project would comply with the County's development review process, including review for compliance with the VCFD Fire Apparatus Access Standard 501 as well as compliance with applicable emergency access standards that would facilitate emergency vehicle access during project construction and operation. Adherence to these requirements and recommendations would further reduce the likelihood of ignition during installation and maintenance of associated infrastructure.

Given that construction activities would require ground disturbance and the use of heavy machinery, the installation of associated infrastructure, such as roads and utility service lines, could potentially result in temporary or ongoing impacts to the environment and could exacerbate wildfire risk by introducing new potential sources of ignition, such as the use of heavy machinery, welding, or other hot work. However, as previously discussed, vegetation would be removed from the site prior to the start of construction, and the site would be graded, which would reduce the likelihood of fire ignition during construction activities. Additionally, water and fire hydrants would be installed to comply with Ventura County Fire Code as described in Section 5 of the FPP. Installation and maintenance of this infrastructure would not exacerbate fire risk on the project site or the surrounding lands. The site itself and the land immediately surrounding the site is mostly agricultural land use, with a small residential area to the north and an industrial area to the east. Project roads would provide improved access for firefighters. In addition, on-site roads would act as fire breaks and limit the spread of a surface fire onto or off the Project site. As such, it is not anticipated that associated infrastructure for the project would exacerbate wildfire risks. The project would be consistent with the General Plan PEIR, General Plan policies, as demonstrated by the FPP and WES prepared for the project, and project-specific design features and fire safety measures would aid in reducing the risk. There are no site-specific conditions or impacts peculiar to the project related to the installation or maintenance of associated infrastructure. Therefore, impacts would not be more severe than analyzed in the previously certified PEIR.

Impact WIL-4 If located in or adjacent to an HFA, a project may have a significant impact if it would substantially impair or obstruct implementation of the Ventura County Emergency Operations Plan.

Policy HAZ-12.2 requires the County to maintain and periodically update the Ventura County Emergency Operations Plan (EOP) and the Ventura County Multi-Hazard Mitigation Plan. Independent of buildout anticipated under the 2040 General Plan, such as the Project, the EOP is required to be updated every three years and MHMP every five years. The County relies on the EOP to guide responsibilities and decisions during an emergency. Consistency with the EOP promotes safety for all residents and visitors of the project site. There are no established evacuation timeframe thresholds set by the County, or the state, that must be met to ensure the project would not impair an adopted emergency response plan or evacuation plan, thus consistent with the EOP is evaluated qualitatively. The project includes multiple unique features that enhance safety of the project site and make it unlikely to conflict with the EOP. A Fire Protection Plan (FPP) and Wildfire Evacuation Study (WES) have been prepared for the project, outlining project-specific requirements and safety features. All roadways and structures have been designed with code-compliant fire access and fire-resistant building materials and comply with adopted codes and standards, or otherwise accommodate for code discrepancies (e.g., the project would include an additional 100 feet of FMZ for a total of 200 feet of FMZ). The purpose of the FPP and WES is to memorialize the fire safety requirements and evaluate the project's consistency with relevant emergency evacuation plans and emergency response plans, disclose the prevention and minimization regulations and measures applicable to the project, as well as provide emergency preparedness information and resources to increase occupant preparedness and facilitate efficient response in the event of an emergency. The 200-foot FMZ around the entirety of the project provies a redundant layer of fire protection that complements the aforementioned roadways and fire-resistant building materials. Because of the safety features included in project design, it is unlikely that project occupants would impair the EOP.

Therefore, the Project would not substantially impair or obstruct implementation of the Ventura County Emergency Operations Plan. There are no site-specific conditions or impacts peculiar to the project that were not addressed in the PEIR, and the project would not result in impacts more severe than analyzed in the previously certified PEIR.

Impact WIL-5 If located in or adjacent to an HFA, a project may have a significant impact if it would substantially impair or obstruct primary or alternative evacuation routes.

There are currently no significant standards for evacuation travel time for the Project area or established in the CEQA Guidelines. Public safety, not time, is generally the guiding consideration for evaluating impacts related to emergency evacuation. The County considers a Project's impact on evacuation significant if the Project would significantly impair or obstruct primary or alternative evacuation routes. In an evacuation, the Project occupants would primarily utilize SR-33 and U.S. Route 101, as illustrated in Figure 4 – Evacuation Routes, of the WES.

Safely undertaking large-scale evacuations may take several hours or more and require moving people long distances to designated areas. Further, evacuations are fluid and timeframes may vary widely depending on numerous factors, including, among other things, the number of vehicles evacuating, the road capacity to accommodate those vehicles, occupants' awareness and preparedness, evacuation messaging and direction, and on-site law enforcement control.

Notwithstanding evacuation challenges and variables, the success rate in the County in safely managing both mass and targeted evacuations is very high. For example, the 2017 Thomas Fire caused 31 evacuation orders to more than 90,000 residents, with CAL FIRE and VCFD reporting 1 civilian and 1 firefighter fatality (Ventura County All Hazards Evacuation Plan, 2024). Losses of life in virtually every large wildfire were related to persons who ignored initial evac-

uation warnings, many of whom were located in rural areas with long, exposed evacuation routes. Technological advancements and improved evacuation strategies learned from prior wildfire evacuation events have resulted in a system that is many times more capable of managing evacuations. With the technology in use today in the County, evacuations are more strategic and surgical than in the past, evacuating smaller areas at highest risk and phasing evacuation traffic so that it flows more evenly and minimizes the surges that may slow an evacuation. Mass evacuation scenarios where large populations are all directed to leave simultaneously, resulting in traffic delays, are thereby avoided, and those populations most at risk safely evacuate. As implemented in past wildfire evacuations, an early evacuation of the area may occur several or more hours prior to actual threatening conditions at the Ventura Ranch Farmworker Housing Project site, depending on conditions and fire spread projections.

Based on the typical road capacity, an evacuation of the Project site and surrounding land uses, under worst-case conditions, would take approximately 59 minutes to evacuate if all traffic was using the SR-33. While one cumulative project has been identified in Casitas Springs, located approximately 2.5-3 miles north of the Project site, this project is located outside of the study area. As such, an existing plus cumulative project scenario with and without the Ventura Ranch Farmworker Housing Project has not been included in this study. Cumulative impacts would be limited to ambient growth, which would not contribute enough evacuation traffic to result in a significant impact on evacuation.

As discussed in the WES, the Project would provide emergency managers the alternative option of recommending occupants to temporarily seek refuge on site in fire-resistant buildings or within the converted landscapes and hardscapes that would not readily facilitate wildfire spread. This would provide emergency managers with a safer alternative to risking a late evacuation. Additionally, the Project would provide a new north/south evacuation route that would provide secondary access for the Project as well as the community to the north. Further, the Project does not propose to cut off or otherwise modify existing evacuation routes. Considering these facts and others presented herein, the Project would not expose people to a significant risk of loss or death involving wildland fires related to evacuation, would not interfere with evacuation response planning, and would not result in inadequate emergency access. The project would be consistent with the General Plan PEIR, General Plan policies, as demonstrated by the FPP and WES prepared for the project, and project-specific design features and fire safety measures would aid in reducing the risk and potential impacts to evacuation. There are no site-specific conditions or impacts peculiar to the project related to drainage patterns, runoff, on flooding that were not addressed in the PEIR. Thus, the project would not result in impacts related to evacuation more severe than the previously approved PEIR.

STEP 1: DETERMINE PROJECT APPLICABILITY

Instructions:
For new development projects, answer yes, no, or NA to questions (1) - (10) below.
For redevelopment projects , answer yes, no, or NA to questions (11) - (13) below.

NEW DEVELOPMENT PROJECTS	
Does the new development project fall within categories (1) - (10) below?	
Project Type and/or Characteristics	**Y/N/NA**
1) Development projects equal to 1 acre or greater of disturbed area that adds more than 10,000 square feet of impervious surface area **→go to Step 2**	Y
2) Industrial parks with 10,000 square feet or more of total altered surface area **→go to Step 2**	N
3) Commercial strip malls with 10,000 square feet or more of impervious surface area **→go to Step 2**	N
4) Retail gasoline outlets with 5,000 square feet or more of total altered surface area **→go to Step 2**	N
5) Restaurants (Standard Industrial Classification (SIC) of 5812) with 5,000 square feet or more of total altered surface area **→go to Step 2**	N
6) Parking lots with 5,000 square feet or more of impervious surface area, or with 25 or more parking spaces **→go to Step 2**	N
7) Streets, roads, highways, and freeway construction of 10,000 square feet or more of impervious surface area **→ go to Roadway Projects**	N
8) Automotive service facilities (Standard Industrial Classification (SIC) of 5013, 5014, 5511, 5541, 7532-7534 and 7536-7539) of 5,000 square feet or more of total altered surface area **→go to Step 2**	N
9) Projects located in or directly adjacent to, or discharging directly to an Environmentally Sensitive Area (ESA), where the development will: a. Discharge stormwater runoff that is likely to impact a sensitive biological species or habitat; and b. Create 2,500 square feet or more of impervious surface area **→go to Step 2**	N
10) Single-family hillside homes (see Section 2 of the TGM for specific requirements) **→go to SF Hillside**	N

Project Name: Ventura Ranch

PROJECT APPLICABILITY, CONT.

REDEVELOPMENT PROJECTS	
For redevelopment projects that fall within categories (1) through (9) above, and that conduct land-disturbing activities that result in the creation, or addition, or replacement of 5,000 square feet or more of impervious surface area on an already developed site, answer questions 11-13 below.Existing single-family dwelling and accessory structures are exempt from redevelopment projects unless such projects create, add, or replace 10,000 square feet of impervious surface area.	
Project Type and/or Characteristics	**Y/N/NA**
11) Projects where redevelopment results in an alteration to more than fifty percent of impervious surfaces of a previously existing development, and the existing development was not subject to the post development stormwater quality control requirements of Board Order 00-108, these projects must mitigate the entire redevelopment project area **→go to Step 2**	N/A
12) Projects where redevelopment results in an alteration to more than fifty percent of impervious surfaces of a previously existing development, and the existing development was subject to the post development stormwater quality control requirements of Board Order 00-108, the project must mitigate only the altered portion of the redevelopment project area and not the entire project area **→go to Step 2**	N/A
13) Projects where redevelopment results in an alteration of less than fifty percent of impervious surfaces of a previously existing development these projects must mitigate only the altered portion of the redevelopment project area and not the entire project area **→go to Step 2**	N/A

Project Name: Ventura Ranch

STEP 2: ASSESS SITE CONDITIONS

Provide an assessment of the project site using the following tables

New Development Project General Characteristics

General Project Characteristics	Area (acres)
Total Project Site Area	18.00
Total Disturbed Area	18.00
Total Existing (Pre-Project) Impervious Area	0.39
Post-Project Impervious Area [1]	11.70
Area of Green Roof (ET-1) [1]	0.00
Area Draining to Hydrologic Source Controls (ET-2) [1]	0.00
Revised Post-Project Impervious Area	11.70
Project Imperviousness (%)	65.00%

Redevelopment Project General Characteristics

General Project Characteristics	Area (acres)
Total Project Site Area	0.00
Total Altered Area [6]	0.00
Total Existing (Pre-Project) Impervious Area	0.00
Was existing (pre-project) impervious area subject to post-development stormwater quality control requirements? [2]	0.00
Amount of Existing Impervious Area Altered [3]	0.00
Amount of Impervious Area Added	0.00
% Alteration of Existing Impervious Area [4]	N/A
Post-Project Impervious Area (Impervious Area to be Mitigated) [1], [4]	0.00
Area of Green Roof (ET-1) [1]	0.00
Area Draining to Hydrologic Source Controls (ET-2) [1]	0.00
Revised Post-Project Impervious Area	0.00
Project Imperviousness (%) [5]	

Project Name: Ventura Ranch

Project Description

Briefly describe project:
328 apartment units of farm worker housing on 18-acre site along Ventura Avenue in the unincorporated portion of Ventura County.
Describe current and proposed zoning and land use designation:
The existing site is an orchard with a single-family residence and barn. Currently zoned ECU- Agricultural, Open Space
Describe topography of project area. Identify low and high points and the location of steep slopes (provide a range of grades):
The site has a general slope of 4% from east to west and drains as surface runoff into Ventura Avenue. Runoff from the site drains north towards the catch basins within Ventura Avenue and is tributary to the Ventura River and eventually the Pacific Ocean.
Describe the site's soil types (A, B, C, D) and geological conditions
Ventura County has identified the soil number for this site as 4 and the rainfall zone as Lower Ventura River. AGS has prepared a soils report for the site dated 12/16/2022 and a response letter to County comments dated 8/16/2023. The soils report indicates that the alluvium consists of clayey sand and silty sand. The corrected infiltration rates range from 0.3-3.9 inches per hour. *Attach soil type information*

Project Name: Ventura Ranch

Project Description, cont'd

Describe the site's groundwater conditions (e.g. depth to seasonal high groundwater):
The historically highest groundwater level below the subject site ranges from approximately 17 to 18 feet below the existing ground surface at the extreme west end of the site, to deeper than 40 feet below the existing ground surface within the entire eastern half of the site. Water was not encountered during exploration to a depth of 40.5'.

Is there offsite drainage on the site? If so, identify the location(s) and source(s) of offsite drainage and the volume of water running onto the site:
The 5.4 acres to the east of the site will run onto the site. This hillside does not have any impervious area with a general grade of 40%. The Q10 is anticipated to be near 6 cfs.
Describe any existing utilities within the project area that would limit the possible locations of certain BMPs:
There will be no utilities wihtin the site come the start of construction. The irrigation liens and water meter will be removed during demo.
Describe any environmentally sensitive areas (e.g. riparian areas, wetlands) within the project area:
None

Geotechnical considerations:	
Does the site contain any of the following characteristics:	**Y/N/NA**
Collapsible Soil	N
Expansion Soil	N
Potential for seismically-inducted soil liquefaction	N
Additional considerations:	
Attach relevant geotechnical information	

Project Name: Ventura Ranch

STEP 2: POLLUTANTS OF CONCERN

Pollutants of Concern (See Section 3.3 of TGM)

Activity / Potential Land Uses	Potential Pollutant*								
	Sediment	Nutrients	Metals	Pesticides	Oxygen Demanding Substances	Toxic Organics	Oil & Grease	Bacteria	Trash and Debris
Parking Lots	X		X		X	X			X
Home Subdivisions	X	X			X			X	X
Other [fill in if necessary]									
Other [fill in if necessary]									

*Denote potential pollutant with "x"

Receiving Waterbody Listings (see Section 3.3. of TGM)

Receiving Waterbody (watershed indicated in parentheses)	**Constituent Group [7]**	**Distance to Project (ft)**
Ventura River (Ventura River)	Bacteria, Nutrients	1600.00
Other [fill in if necessary]		

[1] Applicant should enter post-project impervious cover prior to accounting for green roof and hydrologic source control (HSC) credits. Volume reduction provided by green roofs and HSCs are accounted for implicitly in the sizing calcuations for BMPs by assuming the roof area covered by a green roof or the area draining to a HSC is pervious rather than impervious when caluclating the runoff coefficient for the site. Green roofs and HSCs are not required to be considered for all project locations and types. In order to obtain credit, Green Roofs and HSCs must be designed as specified in the TGM. Additional detail on Green Roofs (ET-1) and HSCs (ET-2) can be found in Section 6 of the TGM.

[2] Land-disturbing activity that results in the creation or addition or replacement of less than 5,000 square feet of impervious surface area on an already developed site, or that results in a decrease in impervious area which was subject to the post development stormwater quality control requirements of Board Order 00-108, is not subject to mitigation unless so directed by the local permitting agency

[3] Redevelopment does not include routine maintenance activities that are conducted to maintain the original line and grade, hydraulic capacity, or original purpose of the facility or emergency redevelopment activity required to protect public health and safety. Impervious surface replacement, such as the reconstruction of parking lots and roadways, that does not disturb additional area and maintains the original grade and alignment, is considered a routine maintenance activity. Agencies' flood control, drainage, and wet utilities projects that maintain original line and grade or hydraulic capacity are considered routine maintenance. Redevelopment also does not include the repaving of existing roads to maintain original line and grade.

[4] "% Alteration of Existing Impervious Area" determines the 50% threshold which is key in determining portion of site that must comply with post-construction requirements - see Step 1 redevelopment categories for more detail. The amount of "Post Project Impervious Area" that must adhere to post-construction requirements is dependant on 50% threshold

[5] "Project Imperviousness" is calculated using the "Total Project Area" except when redevelopment projects that must mitigate only the altered portion of the redevelopment project area. In this case, the "Total Disturbed Area" is used to calculate "Project Imperviousness"

[6] For the purposes of this calculation, Total Altered Area shall mean any area that is altered as a result of land disturbance, such as clearing, grading, grubbing, and excavation. This excludes areas used exclusively for temporary stockpiling.

[7] If a waterbody is listed for "toxicity" and the cause and/or contribution to toxicity is known, then the consituent group known to contribute to toxicity are listed here (in lieu of listing "toxicity")

Project Name: Ventura Ranch

STEP 3: APPLY SITE DESIGN PRINCIPLES AND TECHNIQUES

Provide a brief description of site design principles and techniques included within the proposed project site.

Site Design Measures [1]	Included? Y/N/NA	Brief Description of the Site Design Measure
Site Planning	Y	Site was designed infiltration basins at the low end of the site in an area that will allow infiltration into the native soil
Protect and Restore Natural Areas	N	The site will be cleared and grubbed of trees then fully developed
Minimize Land Disturbance	Y	Earthwork was attenmpted to be minimized, but fire department access requirements dictated the earthwork
Minimize Impervious Cover	Y	Landscaping and recreational areas were maximized to the extent feasible
Apply LID at Various Scales	Y	There is pretreatment through a hydrodynamic separator
Implement Integrated Water Resource Management Practices	N/A	

[1] Refer to Section 4.2 - 4.7 of the TGM for applicable Design Criteria.

Project Name: Ventura Ranch

STEP 4: APPLY SOURCE CONTROL MEASURES

Provide a brief description of the source control measures included in the proposed project site.

Site-Specific Source Control Measures[1]	Included? Y/N/NA	Brief Description of the Source Control Measure
S-1: Storm Drain Message and Signage	Y	Do not dump signs will be installed
S-2: Outdoor Material Storage Area Design	N/A	
S-3: Outdoor Trash Storage and Waste Handling Area Design	Y	Trash enclosure meeting County standards will be constructed
S-4: Outdoor Loading/Unloading Dock Area Design	N/A	
S-5: Outdoor Repair/Maintenance Bay Design	N/A	
S-6: Outdoor Vehicle /Equipment/ Accessory Washing Area Design	N/A	
S-7: Fueling Area Design	N/A	
S-8: Proof of Control Measure Maintenance	N/A	

[1] Refer to Fact Sheets in Section 5 of the TGM for detailed information and design criteria

Project Name: Ventura Ranch

STEP 5: APPLY BMPS TO REDUCE EIA TO <=5%

New development and redevelopment projects (Categories 1-6, 8, and 9) must reduce EIA to <=5%

Step 5a: Calculate Allowable EIA

EIA is defined as impervious area that is hydrologically connected via sheet flow over a hardened conveyance or impervious surface without any intervening medium to mitigate flow volume.

The allowable "EIA" for a project is calculated as:

$$EIA_{allowable} = (A_{project})*(\%_{allowable}) \quad \text{Equation 2-1}$$

Where:

$EIA_{allowable}$ = The maximum impervious area from which runoff can be treated and discharged offsite (and not retained onsite) [acres]

$A_{project}$ = The total project area [acres] [1]

$\%_{allowable}$ = 5 percent

Input:		**Units**
$A_{project}$ [1]	18.00	Acres
$\%_{allowable}$	5.00%	Percent
$EIA_{allowable}$	**0.90**	Acres

Step 5b: Calculate Impervious Area to be Retained

The impervious area from which runoff must be retained onsite is the total impervious area minus the EIA allowable, which should be calculated as follows:

$$A_{retain} = TIA - EIA_{allowable} = (IMP*A_{project}) - EIA_{allowable} \quad \text{Equation 2-2}$$

Where:

A_{retain} = the drainage area from which runoff must be retained [acres]

TIA = total impervious area [acres]

IMP = imperviousness of project area (%)

Input:		**Units**
Imperviousness	65.00%	
$A_{project}$ [1]	18.00	Acres
$EIA_{allowable}$	0.90	Acres
A_{retain}	**10.80**	Acres

Project Name: Ventura Ranch

BMPS TO REDUCE EIA TO <=5%, CONT.

Step 5c: Calculate the Volume to be Retained (SQDV)

The runoff volume that is to be retained onsite should be calculated using Equation 2-3 below:

$$V_{retain} = C*(0.75/12)*A_{retain}$$ Equation 2-3

Where:

V_{retain} = The stormwater quality design volume (SQDV) that must be retained onsite [ac-ft]

C = runoff coefficient (equals 0.95 for impervious surfaces)

Input:		**Units**
C	0.95	
A_{retain}	10.80	Acres
V_{retain}	0.641	ac-ft
	208,953.5	gallons
	27,932.9	cu.ft.

Continue to Step 5d

Project Name: Ventura Ranch

STEP 5d: SELECT RETENTION BMPs

Select and size Retention BMPs to meet the 5% EIA Requirement. Retention BMPs include INF1-6, RWH-1, and ET 1 and 2. See TGM, Section 6 for more information.

Retention BMPs	Included? Y/N	Drainage Area Retained (acres) [2]	Drainage Area Runoff Coefficient	Volume Retained (SQDV) (ac-ft) [1],[2]	If not applicable, state brief reason
Infiltration BMPs					
INF-1: Infiltration Basin	Y	10.80	0.95	0.641	
INF-2: Infiltration Trench	N		0.95		
INF-3: Bioretention	N		0.95		
INF-4: Drywell	N		0.95		
INF-5: Permeable Pavement	N		0.95		
INF-6: Proprietary Infiltration	N		0.95		
INF-7: Bioinfiltration	N		0.95		
Rainwater Harvesting BMPs					
RWH-1: Rainwater Harvesting	N		2		
			TOTAL Volume Retained	0.641	ac-ft
				208,953.5	gallons
				27,932.9	cu.ft.
			REMAINING Volume to meet 5% EIA requirement	0.000	ac-ft
				0	gallons
				0	cu.ft.

[1] SQDV Methodology #3 used here.

[2] If a Retention BMP is used more than once on a site (i.e., 2 Infiltration Trenches implemented on one site) then drainage area and volume retained shown here should be additive. A separate BMP sizing worksheet (see Appendix E of the TGM) should be submitted for each BMP.

If onsite Retention BMPs cannot feasibly be used to meet the 5% EIA Requirement, move onto Step 5e; if 5%EIA Requirement is met go to Step 7

	Y/N/NA
A completed copy of the applicable "BMP Sizing Worksheet(s)" for the project's Retention BMPs from Appendix E of the TGM is included as an attachment. BMPs must be sized to meet the SQDV or SQDF (See Section 2 Step 7 of the TGM).	Y

VENTURA FARMWORKER HOUSING

SHEET 1 OF 1

Mar 25, 2024

J:\PLA26366\Planning\Exhibits\6366 HYDROLOGY EXHIBIT.dwg Mar 25, 2024, 4:..

Designer:	Jensen Design & Survey, Inc
Project Proponent:	Ventura Ranch Partners
Date:	3/25/2024
Project:	Ventura Farmworker Housing
Location:	Ventura County Unincorporated Area

Type of Vegetation: (Check type used or describe "Other"		Native Grass
		Irrigated Turf Grass
	X	Other

Step 1: Determine Water Quality Design Volume

1-1	Enter Project Area	$A_{project}$=	18.0	ac
1-2	Enter the maximum allowable percent of the Project area that may be effective impervious area (%)(refer to permit), ranges from 5-30% allowable	%allowable=	5	%
1-3	Determine the maximum allowable effective impervious area (ac), $EIA_{allowable} = (A_{project})*(\%allowable)$	$EIA_{allowable}$=	0.90	ac
1-4	Enter Project Impervious fraction, IMP	IMP =	0.65	
1-5	Determine the Project Total Impervious Area (ac) $TIA = A_{project}*IMP$	TIA =	11.70	ac
1-6	Determine the total area from which runoff must be retained (ac), $A_{retain}=TIA-EIA_{allowable}$	A_{retain} =	10.80	ac
1-7	Determine pervious runoff coefficient using Table E-1, C_p	C_p =	0.050	
1-8	Calculate runoff coefficient $C=0.95*IMP + C_p(1-IMP)$	C =	0.95	
1-9	Enter design rainfall depth of the storm (in), P_i	P_i =	0.75	in
1-10	Calculate rainfall depth (ft), $P = P_i/12$	P =	0.0625	ft
1-11	Calculate Water Quality Design Volume (CF) $SQDV = 43560*C*P*A_{retain}$	SQDV =	27932.85	cf

Table 6.4 - Infiltration Facility Safety Factor Determination Worksheet

Factor Category		Factor Description	Assigned Weight (w)	Factor Value (v)	Product (p) p = w*v
A	Suitability Assessment	Soil Assessment Method	0.25	1	0.25
		Predominant Soil texture	0.25	2	0.5
		Soil Variability	0.25	1	0.25
		Depth to groundwater / impervious layer	0.25	2	0.5
		Suitability Assessment Safety Factor S_A =			**1.5**
B	Design	Tributary Area Size	0.25	3	0.75
		Level of pre-treatment / expected sediment loads	0.25	1	0.25
		Redundancy	0.25	3	0.75
		Compaction during construction	0.25	2	0.5
		Design Safety Factor S_B =			**2.25**

Combined Safety Factor = S_A * S_B = 3.375

INF-1 - Infiltration Basin

Designer:	Jensen Design & Survey, Inc
Project Proponent:	Ventura Ranch Partners
Date:	3/25/2024
Project:	Ventura Farmworker Housing
Location:	Ventura County Unincorporated Area

Type of Vegetation: (Check type used or describe "Other"

_____ Native Grass
_____ Irrigated Turf Grass
_____ Other

Step 2: Determine the design percolation rate

2-1	Enter measured soil percolation rate (in/hr) 0.5 in/hr minimum. $P_{measured}$	$P_{measured}$=	0.77	in/hr
2-2	Determine percolation rate correction factor, S_A based on suitability assessment (see Section 6 INF-1, Table 6-2)	S_A =	1.5	
2-3	Determine percolation rate correction factor, S_B based on design (see Section 6 INF-1)	S_B =	2.25	
2-4	Calculate Combine safety factor, $S = S_A * S_B$	S =	3.375	
2-5	Calculate the design percolation rate (in/hr) $P_{design} = P_{measured}/S$	P_{design} =	0.228	in/hr

Step 3: Calculate the surface area

3-1	Enter required drain time (hours, 72 hours max, t	t =	72	hr
3-2	Calculate max. depth of runoff that can be infiltrated within the t (ft), d_{max} = $P_{design}*t/12$	d_{max} =	1.4	ft
3-3	For Basins, Select ponding depth dp such that $d_p <= d_{max}$	d_p =	1.4	ft
3-6	Enter the time to fill infiltration basin with water (sue 2 hours for most designs), T	T =	2	hrs
3-7	Calculate Infiltrating surface area for infiltration basin $A_b = SQDV/(TP_{design}/12+d_p)$	A_b =	19424.5	sf

Geological and Geotechnical Engineering Study
Proposed Farmworker Housing Development
4884 N. Ventura Avenue
Ventura, California

In accordance with our proposal and your authorization, Advanced Geotechnical Services, Inc., (AGS) has prepared this geological and geotechnical engineering study report for the proposed farmworker housing development to be constructed at the subject site. This report presents the results of our data research, site reconnaissance, subsurface exploration, laboratory testing, and our professional opinions regarding the geological and geotechnical engineering factors that may affect the proposed development.

Based on the results of this study, it is our opinion that the site is *suitable* for construction of the proposed development, with some modifications to the proposed scope and plans that were provided to our office, as discussed herein. The recommendations contained within this report should be properly incorporated in the design, and implemented during construction.

This opportunity to be of service is sincerely appreciated. This report should be read from cover to cover to understand its limitations and to avoid taking a recommendation out-of-context. If you have any questions, or if we may be of any further assistance, please do *not* hesitate to call. We look forward to being of continued service.

Respectfully submitted,
Advanced Geotechnical Services, Inc.

1. INTRODUCTION

1.1 General Remarks

This geological and geotechnical engineering study has been prepared for the proposed farmworker housing development to be constructed at the subject site. The purposes of this study are to (1) identify onsite soil and geologic conditions that may affect the proposed project, (2) evaluate the seismicity of the site and potential seismic hazards, and (3) provide geotechnical recommendations for development of the site. This report presents the findings of our data review, subsurface exploration, laboratory testing, engineering analyses and evaluations, and our conclusions and recommendations.

Appendices are attached following the main report. Appendix A includes details related to the field exploration program, and the boring and test pit logs; Appendix B includes the laboratory test results; Appendix C includes the seismic design criteria; Appendix D includes the references used in this study, and the Figures and Plates referenced in this report are included in Appendix E.

1.2 Scope of Services

This geotechnical engineering study included:

a. Site observation and review of geotechnical and geologic data related to the general study area. A *Site Location Map*, based upon a recent aerial image obtained from the interactive web program Google Earth (2022), which shows a broad view of the general area where the subject site is located is provided as Figure 1, and an *Existing Site Plan*, which is based upon an aerial image dated December 2019, obtained from the interactive County View web program maintained by the County of Ventura (2022), showing a more detailed view of the site, is provided as Plate 1. A *Topographic Site Plan*, based upon a recent topographic plan provided by Jensen Design and Survey, Inc., is included as Plate 2.

b. Review of the project plan provided to our office by Jensen Design and Survey, Inc., which consisted of a *Preliminary Grading Plan for Ventura Ranch*, dated July 25, 2022. A copy of this plan has been utilized as the base map for the *Proposed Site Plan*, which is included as Plate 3 of this report.

c. Reconnaissance of the subject site and in the immediate vicinity of the subject site.

d. The excavation, sampling, and logging of 5 borings and 16 test pits for geological and geotechnical evaluation, and 4 test pits for infiltration testing. The borings and test pits extended to depths ranging between approximately 5 and 50.5 feet below the existing ground surface. The borings were excavated utilizing a truck-mounted, 8-inch diameter hollow-stem auger drilling equipment, and the test pits were excavated utilizing a backhoe. The exploratory boring and test pit locations were determined in the field using a tape measure, and approximate reference points, and their approximate locations are shown on the attached Plates 1, 2 and 3, titled *Existing Site Plan*, *Topographic Site Plan*, and *Proposed Site Plan*, respectively. The actual boring and test pit locations may deviate slightly from these locations. The boring and test pit logs are included in Appendix A, along with a general description of the field operations.

e. Laboratory testing of selected samples to determine the engineering properties of the onsite earth materials. The results of the laboratory testing are presented in Appendix B, and on the boring and test pit logs in Appendix A. Soil samples will be *discarded* 30 days after the date of this report, unless this office receives a specific request and fee to retain the samples for a longer period of time.

f. Determination of seismic parameters for potential onsite ground motion, and current building code seismic design parameters.

g. Engineering analysis of the data and information obtained from our field study, laboratory testing, and literature review.

h. Development of geotechnical recommendations for site preparation, grading, building foundations, floor slabs, underground utility trenches, temporary excavations, pavement, stormwater infiltration, and drainage.

i. Preparation of this report summarizing our findings, conclusions, and recommendations regarding the geological and geotechnical aspects of the project site.

The scope of this geotechnical engineering study did *not* include an assessment of potential environmental issues.

1.3 Site Description

The subject site consists of an approximately 18.24-acre sized parcel of land, identified as APN 063-0-110-090, 4884 N. Ventura Avenue, in the unincorporated County area north of the City of Ventura, California, as shown on the attached Figure 1, *Site Location Map*, and Plate 1, *Existing Site Plan*. Figure 1 was created utilizing an image obtained from the Google Earth (2022) online web app, and Plate 1 was created utilizing an image obtained from the Ventura County View (2022) website, utilizing the December 2019 aerial image as a basemap.

At the time of our field exploration program, the majority of the subject site was an actively operating orchard, with an existing single-family residence and barn located in the southwestern corner of the site, as shown on the enclosed *Existing Site Plan*, Plate 1, and *Topographic Site Plan*, Plate 2. The subject site is bounded by existing single-family residences to the north, by Ventura Avenue and Norway Drive to the west, by an existing farm property to the south, with a two-story residence and other miscellaneous structures, and by an undeveloped hillside area to the east.

The general topography of the majority of the subject site (excluding the existing landslide area at the east end of the site, as delineated on the attached Plates 1, 2, and 3, and discussed in greater detail below), slopes gently down towards the west to southwest, with a gradient ranging from a maximum of approximately 7.5% in the northeast corner of this area, to a minimum of approximately 2% in the southwest corner. The existing topographic gradient generally increases from southwest to northeast, with the westernmost portion of the property at an approximate elevation of 203, and the easternmost portion of the property at an approximate elevation of 266, as shown on the *Topographic Site Plan* included as Plate 2.

In the northwestern portion of the site, along Norway Drive, and extending southward along a portion of Ventura Avenue, the grade on the subject site drops abruptly up to a maximum of approximately 6 to 7 feet down towards the property line. Along portions of the north side of the site, various retaining walls up to several feet in height either retain the subject site above the adjacent grades within the backyards of the existing residences, or vice-versa.

The easternmost portion of the subject site begins to slope with an increasing gradient starting at approximate elevation 232, as shown on the *Topographic Site Plan* included as Plate 2. The gradual increase in slope gradient progresses easterly, where in the proximity of the eastern property limits, the slope gradient increases sharply from approximately 3:1 (32%) within the subject site, with the offsite east ascending slope having a gradient locally of as steep as approximately 1:1 (45%), ascending to an approximate elevation of 480 (as determined from Google Earth).

Based upon surficial and topographic expression, our field exploration and reconnaissance efforts, and our review of available historical aerial photographs dating back to January 1927, it is our professional opinion that this east

ascending slope has experienced pre-historic landslide actively, resulting in the existing over-steepened offsite slope and the deposition of landslide debris generated from the landslide event upon this slope and within the easternmost portion of the subject site. The approximate limits of the areas interpreted to be underlain by landslide debris have been indicated on the *Existing Site Plan*, *Topographic Site Plan*, and *Proposed Site Plan* included as Plates 1, 2, and 3, respectively, of this report. More detailed descriptions of this portion of the site, and more in depth discussions of this landslide feature are provided in subsequent sections of this report.

1.4 Proposed Development

The currently proposed development is shown on the attached Plate 3, *Proposed Site Plan*, and consists of a total of 29 two to three-story farmworker housing structures, and surrounding driveways, streets and surface parking. A new roughly east-west trending street will connect to Ventura Avenue in the southwestern portion of the site, and a new roughly north-south trending street near the east end of the site will connect to the existing Floral Drive in the northeastern corner of the site. The attached Plate 3 was created utilizing a *Preliminary Grading Plan for Ventura Ranch*, prepared by Jensen Design and Survey, Inc., dated July 25, 2022. Structural loads for the proposed buildings are not expected to exceed approximately 100 to 150 kips for columns, and 1 to 3 kips per foot for walls.

As will be discussed in more detail in subsequent sections of this report, and as shown on the attached Plates 1 through 3, the extreme eastern end of the site (generally east of the proposed new north-south trending street) has been identified during this study as being within an area that had experienced pre-historic landslide activity, and development within this area should not be permitted. The currently proposed development within this area, as shown on the attached Plate 3, consists of three new housing structures, along with surrounding paved driveway and parking areas. This construction at the east end would require a new retaining wall up to 15 feet in height, and new cut slopes up to approximately 22 feet in height, and a maximum 2:1 gradient. This would require the removal of a large volume of earth materials from the toe of the existing landslide, potentially causing instability. As discussed further in this report, removal of earth materials, and/or construction of new habitable structures in this area should not be allowed, however, portions of this area might be suitable for parking or roadways, provided the final site grade is at or above current existing grades everywhere within this existing landslide impacted area. The three new structures that were proposed to be constructed within this area will have to be relocated to elsewhere on the project site, or eliminated.

Along most of the entire south end of the site, and the eastern portion of the north side of the site, the proposed new site grades will slope relatively gently (gradients less than 5:1) down to meet the current existing grades at the property line, and/or match existing grades. Along the western portion of the north side of the site, the sloping gradient down to the property line increases to as much as approximately 2:1. Along the west side of the site, and along the north and south sides of the new east-west trending street near where it connects to Ventura Avenue, there will be retaining walls up to 5 feet in height at the toe of new descending fill slopes.

The grading currently proposed to be performed within the eastern end of the site, as shown on the *Proposed Site Plan* included as Plate 3 of this report, would require substantial modification in order to avoid destabilizing the existing onsite and offsite slopes present within this area, which have been determined to have been impacted by, and/or are the result of pre-historic landslide activity, and to safely transition to the adjacent existing grade and/or proposed future grades. As noted previously, the removal of materials from this portion of the subject site may destabilize the existing slopes, which currently appear to be in stasis, and therefore the currently proposed cuts and retaining walls should be eliminated from the future grading plans. Additionally, due to the potential of offsite erosion upon the over-steepened offsite slope which may result in soil migration onto the easternmost portion of the subject site, it is recommended that no habitable structures be constructed within the easternmost portion of the site. At a minimum, it is recommended that no removals be made or structures created within that portion of the subject site which lies to the east of the interpreted geologic contact between the older alluvium (Qoa) and the landslide debris (Qls), as identified on Plates 1 through 3 of this report.

Site grading throughout the majority of the site (approximately west of the north-south trending roadway near the east end of the site) will consist of the over-excavation and recompaction of the weaker, upper site soils, and the import of approximately 105,000 additional yards of earth materials to raise the existing site grade approximately 0.5 to 9 feet above the currently existing site grade, to establish grade for the building pads, streets, driveways and parking areas, detention/infiltration basin, and for site drainage. In addition, there will be backfill of related new utilities and retaining walls.

2. GEOLOGIC SETTING

2.1 Geology

Geologic conditions beneath the subject property have been interpreted and characterized based upon our review of published and unpublished references, our review of available historical aerial photographs, our onsite reconnaissance, and our subsurface exploration. Our interpretations involve projections of data and assume that geologic conditions are reasonably constant between points of exposure. Work should continue under the review of the Geologist and Geotechnical Engineer to ensure that geologic conditions different from those described below are recognized and evaluated as soon as possible. Certain subsurface conditions such as groundwater levels and the consistency of near-surface soils will vary with the seasons.

The subject site is located within the Ventura USGS 7.5-minute quadrangle. According to Dibblee (1988), the subject site is underlain by older alluvial materials (Qoa), as shown on the enclosed *Dibblee Regional Geological Map*, Figure 2. According to the *Geologic Map of the Ventura 7.5' Quadrangle* (USGS, 2003), as shown on the attached *USGS Regional Geological Map*, Figure 3, the subject site is underlain by younger alluvial fan deposits classified as Qhf on this map, although the graphical age correlation shows this material as being an 'older' younger alluvial fan material (i.e., within the first half of the Holocene).

Although not identified on the above referenced regional geologic maps, our onsite exploration and reconnaissance programs, and our review of historical aerial photographs indicate that the natural slope which ascends eastward within the eastern portion of the site, continuing offsite with a maximum estimated total slope height of approximately 250 feet, is the result of pre-historic landslide activity. The in-place bedrock material which composes the ascending slope, where exposed in outcrops at the existing ground surface and as encountered in our exploratory excavations, has been determined to consist of Pliocene age sedimentary bedrock of the Pico Formation (Tp and Tps), defined by Dibblee (1988) as consisting of "mostly gray claystone, vaguely bedded, and few thin strata of sandstone" (Tp) and "mostly light gray to tan sandstone, well bedded, in some places pebbly; includes some interbedded claystone, as above" (Tps) and defined by the USGS as "composed of claystone, siltstone, sandstone, locally pebbly; generally susceptible to landsliding". Intact bedrock material, consisting of pebble and cobble rich sandstone materials, are observed to be exposed in the upper most portions of the east ascending slope, and light gray to tan sandstone materials were observed to be exposed in outcroppings located to the north of Test Pit TP-3 and in the bottom of Test Pit TP-2, while olive siltstone was recovered from the bottom of Boring B-3.

Landslide debris is observed to be present at the surface on the lower portions of the east ascending slope, extending westward into the subject site, and was encountered in Borings B-2 and B-3, and Test Pits TP-1 through TP-6, all excavated within the eastern portion of the subject site, and/or the western portion of the adjacent site to the west. The landslide debris was observed to generally consist of silt sand, with minor to abundant gravel and small cobble to small boulder sized inclusions, which is derived from mass wasting of the Pico Formation. The landslide debris appears to mantle the older alluvium (Qoa) in Boring B-2, however it appears that the older alluvium may mantle the landslide debris at the surficial contact indicated on Plates 1 through 3 of this report, which indicates that deposition of the older alluvium began before and continued after the landslide event(s) began and ceased.

More detailed descriptions of the earth materials encountered during the course of our study are provided in the following sections, and in the boring and test pit logs included in Appendix A of this report.

2.2 Faulting

Southern California is a tectonically active region subject to hazards associated with earthquakes and faulting. Faults are classified as either active, potentially active, or inactive. Active faults are defined by the State of California as faults that have exhibited surface displacement within the last 11,000 years. Potentially active faults are defined by the State as those with a history of movement between 11,000 and 1.6 million years ago. Alquist-Priolo Earthquake Fault Zones are zones that have been established by the State that contain active surface fault traces, and projects that are located within these zones require that a fault investigation be performed to determine if active faulting affects the site.

There are no known active, potentially active, or inactive faults mapped on the subject site, and the closest mapped fault to the subject site is the Red Mountain Fault Zone, which is shown by Dibblee as being located as close as approximately 0.82 miles northwest of the subject site, as shown in the upper left corner of the attached *Dibblee Regional Geological Map,* Figure 2. The Red Mountain Fault Zone has been identified as being a thrust fault, with most likely recent surface rupture during the Holocene to Late Quaternary period, and a probable magnitude (M_W) of 6.0 to 6.8 (SCEDC, 2013). This fault, however, is *not* located within an Alquist-Priolo Earthquake Fault Zone.

The attached Figure 4, *Earthquake Fault and Seismic Hazard Zones Map* (CDMG, 1978; CGS, 2003), shows that the area where the subject site is located is not within an Alquist-Priolo Earthquake Fault Zone, or in close proximity to any zones. The nearest Alquist-Priolo Earthquake Fault Zone is located approximately 3.46 miles south of the subject site, further to the south of the area shown on the enclosed Figure 4.

3. EARTH MATERIALS AND SUBSURFACE CONDITIONS

3.1 Older Alluvium (Qoa)

Older alluvial soils were encountered at the ground surface, and extending to the full depths explored throughout the entire roughly level to gently sloping portion of the site, roughly west of the proposed new north-south trending street to be located near the east end of the site. Older alluvial soils may have also been encountered at a depth of approximately 25 feet in Boring B-2, below the landslide debris, and at the ground surface in Test Pit TP-4. The older alluvium encountered near the existing ground surface has been observed to consist predominantly of naturally deposited clayey sand and silty sand, present in a generally slightly moist to moist and dense condition. More detailed earth material profiles are provided on the enclosed boring and test pit logs in Appendix A.

3.2 Landslide Debris (Qls)

Landslide debris was encountered at the ground surface in Borings B-2 and B-3, and Test Pits TP-1 through TP-6, although the material encountered at the ground surface in TP-4 might have been an older alluvium. All of these borings and test pits were excavated within the eastern portion of the study area. The landslide debris was observed to generally consist of silty sand, with minor to abundant gravel and small cobble to small boulder sized inclusions, which is derived from mass wasting of the Pico Formation. The landslide debris was observed to generally be present in a slightly moist and dense condition. More detailed earth material profiles are provided on the enclosed boring and test pit logs in Appendix A.

3.3 Pico Formation Bedrock (Tp)

Bedrock of the late Pliocene age Pico Formation was encountered at a depth of 20 feet in Boring B-3, and at a depth of approximately 3.5 to 5.5 feet (sloping contact) in Test Pit TP-2, and both of these were excavated offsite at the east end of the study area, as indicated on Plate 1 through 3. The bedrock encountered at the bottom of Boring B-3 was observed to consist of olive siltstone, while the bedrock encountered in the bottom of Test Pit TP-2 was observed to consist of white to tan sandstone. Outcroppings visible on the east ascending offsite slope exposed pebble and cobble rich sandstone materials within the uppermost portions of the slope, and tan to light gray sandstone materials were observed to be exposed at the lower portion of the slope.

More detailed earth material profiles are provided on the enclosed boring and test pit logs in Appendix A.

3.4 Soil Parameters

3.4.1 Compaction

Compaction curves were developed in this study for representative samples of the upper onsite soils, to determine the maximum dry density and optimum moisture content, as summarized in the table below. The upper site soils should be over-excavated and recompacted for support of the proposed improvements, as discussed in subsequent sections of this report.

Boring	Depth (ft)	Description	Maximum Dry Density (pcf)	Optimum Moisture Content (%)
B-1	0-5	CLAYEY SAND	121.0	11.0
B-2	0-5	SILTY SAND	126.5	9.0
B-3	0-5	SILTY SAND	129.5	8.0

3.4.2 Compressibility

Consolidation tests were performed on representative undisturbed samples of the onsite soils, and on a remolded sample intended to represent the future compacted fill. The consolidation test results showed a slight to moderate expansion upon inundation with water for some of the samples, negligible to relatively low hydroconsolidation on the remolded sample and majority of the undisturbed samples, and moderate hydroconsolidation on one of the landslide debris samples. Consolidation test results are included in Appendix B.

3.4.3 Shear Strength

Direct shear testing was performed on a remolded sample of the near surface soils to determine the characteristics of a future fill compacted to 90% relative compaction, and on representative undisturbed samples of the native earth materials. The results of the direct shear testing are included in Appendix B.

3.4.4 R-value Testing

A representative sample of the upper site soils was transported to an outside laboratory for R-value testing, and the results are attached in Appendix B. The results showed that the upper site soils have an R-value of 10. Additional R-value testing should be performed on representative samples of the paving subgrade areas throughout the site, at or near the completion of grading, to verify the R-value of the final subgrade soils.

3.4.5 Grain Size Analysis

Grain size testing was performed on representative samples of the earth materials underlying the site by using mechanical sieve analysis, and hydrometer testing. The results of the grain size testing are presented in Appendix B of this report.

3.4.6 Expansion Category

The potential of the soil to swell or expand increases with an increase in soil density, a decrease in initial moisture content (low percent saturation), an increase in clay content, and an increase in the activity of the clay content. Expansive soils change in volume (shrink or swell) due to changes in the soil moisture content. The risk of soil expansion increases with an increase in expansion index.

The expansion indices of the upper site soils were found to be 34, 54 and 87, for samples obtained from Borings B-3, B-2 and B-1, respectively. These expansion values are in the *low* to *medium* expansion category. Expansion index test results are provided on the boring logs in Appendix A.

3.4.7 Corrosivity

The risk of corrosion of construction materials relates to the potential for soil-induced chemical reaction. The rate of deterioration depends on soil resistivity, texture, acidity, and chemical concentration. Representative samples of the upper site soils were transported to an outside laboratory for corrosivity testing, and the results of these tests are attached in Appendix B. Sulfate and chloride concentrations are expressed in mg/kg on a dry weight basis.

Sample Number	Description	pH	Chloride (mg/kg)	Sulfate (mg/kg)	Resistivity (Ohms-cm)
B-1 @ 0'-5'	CLAYEY SAND	8.07	10.33	12.60	14,925
B-2 @ 0'-5'	SILTY SAND	8.52	16.10	76.68	7,299

The soluble sulfate content is less than 1000 mg/kg, which is *negligible* according to ACI 318 (*S0* exposure category), and therefore special considerations for concrete which will be in contact with the onsite soils are *not* required. The corrosivity data should be provided to the project team, AGS does not practice in the field of corrosivity engineering.

3.5 Groundwater

At the time of our field exploration, groundwater was not encountered in any of the borings or test pits, which were excavated to a maximum depth of approximately 40.5 feet below the existing ground surface, where auger refusal was encountered. Based on the enclosed Figure 5, *Depth to Historically High Groundwater Map* (CGS, 2002), the historically highest groundwater level below the subject site ranges from approximately 17 to 18 feet below the existing ground surface at the extreme west end of the site, to deeper than 40 feet below the existing ground surface within the entire eastern half of the site.

Groundwater elevations are dependent on seasonal precipitation, irrigation, land use, and climatic conditions, among other factors, and as a result fluctuate. Therefore, water levels at the time of construction and during the life of the structures may vary from the observations or conditions at the time of our field exploration.

3.6 Field Infiltration Testing

Test Pits P-1 through P-4 were each excavated to a depth of approximately 4 feet below the existing ground surface using a backhoe, in the currently proposed stormwater infiltration area, and also in three possible alternate areas, as provided to our office by Jensen Design and Survey. The approximate locations of the test pits are indicated on the *Existing Site Plan* included as Plate 1, the *Topographic Site Plan* included as Plate 2, and *Proposed Site Plan* included as Plate 3. An approximately 12-inch square by 12-inch deep infiltration test hole was then excavated in the bottom of each test pit utilizing a shovel and other hand operated equipment.

The test holes were then pre-saturated starting 24-hours prior to the beginning of the infiltration testing. At the conclusion of the pre-saturation period, infiltration testing was performed by filling each infiltration test hole with water to approximately 12 inches above the bottom, and recording the drop of the water surface at 30-minute time intervals for a period of 4 hours. The test results are included on the attached Figures 8 and 9.

A summary of the field and corrected infiltration test results is presented in the following table, along with the appropriate correction factors and corrected rates, based on the correction factors for a 12"x12"x12" infiltration test hole, as specified in L.A. County document GS200.2 (2017). The slowest infiltration rate obtained in each test hole was utilized in these calculations:

Test Hole	Stabilized Field Infiltration Rate (minutes/inch)	Stabilized Field Infiltration Rate (inches/hour)	Correction Factor, Per LA County Document GS200.2	Corrected Infiltration Rate (minutes/inch)	Corrected Infiltration Rate (inches/hour)
P-1	21.82	2.75	2.47	53.9	1.11
P-2	14.12	4.25	2.31	32.6	1.84
P-3	8.57	7.00	2.00	17.1	3.50
P-4	8.00	7.50	1.94	15.6	3.86

No grading or compaction should be performed in the area of the proposed infiltration features, *at or near the depth of infiltration*. If any grading is conducted in the infiltration areas which causes compaction, the bottom of

infiltration features should be deepened below any compacted soils, and into undisturbed and uncompacted native soils. It is recommended that infiltration basins be excavated down to the proposed depth of infiltration utilizing an excavator staged *outside the basin*, at least within 2 to 3 feet of the infiltration depth.

A more detailed discussion of, and recommendations for the construction of the currently proposed and alternate infiltration basins is provided in the *Proposed Stormwater Management and Infiltration* section of this report.

4. SEISMICITY

4.1 Seismic Design Criteria

The seismic design of structures based on the 2019 California Building Code (CBC) utilizes the *Maximum Considered Earthquake Ground Motion*. This ground motion and the associated spectral response accelerations are then adjusted for the general type of earth materials within approximately the upper 100 feet underlying the site, termed a *Site Class*. The *Site Class* is based on parameters such as shear wave velocity, standard penetration test resistance, undrained shear strength, and earth material type. For the subject site, which is underlain by deep younger alluvium, the *Site Class* would be 'D', which corresponds to a *stiff soil*.

The site-specific seismic design criteria required by the 2019 CBC were determined utilizing the SEAOC/OSHPD (2022) Seismic Design Maps online web app, utilizing the most current, ASCE 7-16 Standard. The complete output from this web app is attached, and the primary design parameters are summarized in the table below. The *Site Class* option of '*D – Stiff Soil*' was utilized in the analysis.

ASCE Standard	Site Class	F_a	F_v	PGA	PGA_M	S_S	S_1	S_{MS}	S_{M1}	S_{DS}	S_{D1}
7-16	D	1.0	Null*	1.1	1.022	2.108	0.794	2.108	Null*	1.406	Null*

*** See Section 11.4.8 of ASCE 7-16**

Conformance to these criteria does *not* constitute a guarantee or assurance that significant structural damage will *not* occur if a maximum level earthquake occurs. The primary goal of seismic design is to protect life and *not* to avoid all damage, since such design may be economically prohibitive.

4.2 Earthquake Effects

The intensity of ground shaking during an earthquake can result in a number of phenomena classified as ground failure, which include ground rupture due to faulting, landslides, liquefaction, and seismically induced settlement. Other seismic hazards include seiches and tsunamis. Descriptions of each of these phenomena and an assessment of each, as it may affect the subject site, are included in the following sections. The Seismic Hazards Mapping Act of 1990, which became effective in 1991, requires mitigation of seismic hazards to a level that does *not* cause collapse of a building intended for human occupancy, but it does *not* require mitigation to a level of no ground failure or structural damage.

4.2.1 Shallow Ground Rupture

Ground surface rupture occurs when movement along a fault is sufficient to cause a gap or rupture where the upper edge of the fault zone intersects the ground surface. Such ruptures rarely occur as single breaks or are confined to a narrow zone. More commonly, ground rupture associated with faulting is characterized by relatively short segments of faulting that occur over a broad area of the upper plate. In some cases, particularly in unconsolidated alluvial sediments, *secondary ground ruptures* can develop from a number of causes not necessarily related directly to surface rupture of the causative fault. The secondary ground ruptures may be caused by ground shaking, seismic settlement, landslides, and liquefaction.

Since there are *no* known active or potentially active faults passing through the site, the potential for on-site ground rupture due to movement on an underlying fault in *not* considered a significant hazard, although it is a possibility at any site. The potential for ground rupture due to other causes is discussed in the following sections.

4.2.2 Earthquake-Induced Landsliding

Earthquake-induced landslides are slope failures that occur where the horizontal seismic forces act to induce soil failure. Seismic Hazard Maps have been released by the California Geological Survey that delineate areas that have been subject to, or are potentially subject to landsliding as a result of earthquake-induced ground shaking. The majority of the subject site and surrounding area are relatively flat to only gently sloping, and therefore earthquake-induced landsliding is these areas is *not* considered to be a hazard within the majority of the site.

As shown on the *Earthquake Faults and Seismic Hazard Zones Map* (CGS 2003) included as Figure 4 of this report, the offsite slope which ascends to the east of the subject site has been identified as being potentially susceptible to earthquake induced landslide activity.

Furthermore, as detailed in previous sections of this report, our review of historical aerial photographs and our onsite reconnaissance and exploration programs have indicated that pre-historic landslide activity has impacted the easternmost portion of the site, and the existing east ascending slope which ascends offsite beyond the eastern property line. The surficial expression of the landslide feature indicates that movement has not occurred within historic time, and the interpreted interfingering of the landslide deposits with the older alluvium present below the western portion of the site indicate that the landslide activity was not recent.

Due to the presence of fencing near the base of the landslide feature, and the presence of dense vegetation and over-steepened slope faces within the landslide feature, additional exploration within this landslide feature was not feasible at the time of our exploration program. Regional mapping as published by Dibblee (1988) and the USGS (2003), and a measurement taken in an outcropping at the base of the slope, north of Test Pit TP-3, indicate that bedding is favorable with respect to the existing slope geometry, as detailed on *Cross-Section B-B'* included in Plate 4 of this report. Based upon the bedding attitude recorded in Test Pit TP-2, a slight out of slope component of bedding has been indicated on *Cross-Section A-A'*, also included on Plate 4 of this report.

Although the currently proposed development plans, as included as the base map for the *Proposed Site Plan* included as Plate 3 of this report, indicate that grading will be performed and buildings constructed near the base of the east ascending slope, within the area impacted by the existing landslide debris, as detailed elsewhere within this report, it is our recommendation that the proposed development plan be modified to exclude the currently proposed grading, and to remove and/or relocate the three proposed structures within this portion of the site. As a result of these recommended changes, it is our professional opinion that the risk of earthquake induced landsliding impacting the proposed improvements should be considered to be low.

4.2.3 Seiches and Tsunamis

Seiches are an oscillation of the surface of an inland body of water that varies in period from a few minutes to several hours. Seismic ground shaking can induce such oscillations. Tsunamis are large sea waves produced by submarine earthquakes or volcanic eruptions. The site is *not* located close to, or downstream of an inland body of water, and is at an elevation sufficiently above sea level to be outside the zone of a tsunami runup, and therefore the risk of these two hazards is *not* considered pertinent to this site.

4.2.4 Evaluation of Liquefaction Potential

The subject site is *not* located in an area designated as being potentially liquefiable on the State of California Seismic Hazard Zones Map of the Ventura Quadrangle (CGS, 2003), as shown on the attached Figure 4, *Earthquake Fault and Seismic Hazard Zones Map* (potentially liquefiable areas are indicated by the green shading on this map). Therefore, liquefaction is not considered to be a hazard to the subject site, and liquefaction analysis is not required.

4.2.5 Dynamic Dry Settlement

Dynamic dry settlement is the consolidation of relatively loose sandy soils as a result of seismic shaking. The upper site soils will be over-excavated and recompacted, and the underlying earth materials consist of dense to very dense or stiff older alluvial deposits, which would not be considered subject to any measurable dynamic dry settlement due to seismic shaking. Therefore, dynamic dry settlement would not be considered to be a hazard to the subject site.

5. CONCLUSIONS AND RECOMMENDATIONS

5.1 Conclusions and Design Requirements

Based on the findings of our data review, subsurface exploration, laboratory testing, field testing, and engineering analysis, and within the scope of this study, it is the opinion of AGS that construction of the proposed farmworker housing development is *feasible* from a geotechnical engineering viewpoint, with some modifications to the proposed scope and plans that were provided to our office, as discussed herein. The recommendations contained within this report should be incorporated into the project design, and implemented during construction.

5.1.1 Faults / Seismicity

Although there are no known active or potentially active surface fault traces on the subject site, like most of Southern California, the site lies within a seismically active area. Earthquake resistant structural design is recommended, and is required by the building code. Designing structures to be earthquake-proof is generally considered to be impractical, especially for private projects, due to cost limitations. Significant damage to structures may be unavoidable during large earthquakes. Structural design based on the 2019 CBC (California Building Code) structural analysis procedures specifies the use of the seismic parameters given previously in the *Seismic Design Criteria* section. These minimum code values are intended to protect life and may not provide an acceptable level of protection against significant cosmetic damage and serious economic loss. Significantly higher than code parameter values may be necessary to further reduce potential economic loss during a major seismic event.

5.1.2 Hazardous Materials

AGS has *not* been retained to provide any type of environmental assessment of the subject property, *nor* to provide recommendations with respect to any contamination that might be present. AGS does not practice in the field of environmental assessment.

5.1.3 Cut Slopes

Proposed cut slopes are shown at the east end of the site, as indicated on the *Proposed Site Plan* included as Plate 3 of this report. However, as discussed herein, it is recommended that no cuts be made into the existing slope at the east end of the site. No other cut slopes have been proposed elsewhere on the site.

5.1.4 Fill Slopes

Fill slopes are proposed to be constructed on portions of the site as part of the planned development. Fill slopes will be a maximum 2:1 (horizontal:vertical) in gradient, with maximum anticipated heights of approximately 10 vertical feet. The fill slopes should be constructed in accordance with the recommendations presented in the *Site Preparation* section of this report.

5.1.5 Rockfall

Damage to life or property due to rockfall as a result of the construction of the proposed improvements is *not* considered to be a risk at the subject site.

5.1.6 Slope Setback

When located next to a descending 3(H):1(V) slope or steeper, the base of footings for buildings should be a minimum of 5 feet or one-third (⅓) the slope height from the face of slope, whichever is greater, but need *not* exceed 40 feet from the face of slope. When located next to an ascending 3(H):1(V) slope or steeper, the base of footings

for structures should be a minimum of 3 feet, or one-half (½) the slope height from the toe of slope, whichever is greater, but need *not* exceed 15 feet from the toe of slope. *Examples of Slope Setbacks* are included on the attached Figure 6.

5.1.7 Offsite Drainage

Berms should be established at the tops of descending slopes, to divert drainage and prevent it from concentrating and flowing over slope faces, or offsite.

5.1.8 Proposed Stormwater Management and Infiltration

The current plan shows a large detention and infiltration basin near the west end of the site, as shown on the attached Plate 3 of this report. The bottom of this basin as shown on the current plan will require the placement of approximately 4.25 to 8.25 feet of fill above the current existing site grade, and the construction of fill slopes up to a maximum of approximately 10 feet in height overall, and 3 feet above the bottom of the basin, to create the sloping sides of the basin. A primarily granular, permeable compacted fill would have to be imported to create the bottom of this basin, between the depth of initial over-excavation and the finished grade in the bottom of the basin, and it may be difficult and/or costly to find such a large volume of consistent, select granular fill for this purpose. In addition, very extensive, ongoing testing would be required by the Geotechnical Engineer during the import and placement of this material, to verify the consistency, and minimum required permeability.

It's our understanding that the current plan is somewhat preliminary, and if this basin is to be constructed as shown on the attached Plate 2, it would be recommended that the upper 4 feet approximately of existing native soils first be over-excavated and removed, prior to placing the select, primarily granular fill, and relatively permeable compacted fill. It is also recommended that the contact between the imported primarily granular fill and underlying native soils be relatively level. Note that the imported granular material *would* still require the typical minimum 90% relative compaction, in order to maintain the stability of this basin and adjacent slopes, and therefore this material, *when compacted*, will have to be at least as permeable as the underlying native soils. It would also be recommended that the sloping sides within the interior of the basin be lined with an impermeable liner, to at least reduce the migration of the detained water towards the descending perimeter slopes, and also to prevent erosion of the interior slopes. It is recommended that the liner also extend vertically downward from the toe of the interior descending slopes, to the bottom of the permeable import material (the contact with undisturbed native soils), in order to prevent or at least reduce horizontal migration of the detained water towards the exterior slope faces, and reduce the potential for the infiltrated water to daylight in the lower surrounding areas to the north and west of the basin. Another requirement for the descending slopes around the perimeter of this proposed detention/infiltration basin would be that the earth materials utilized to construct these slopes be relatively cohesive, and that a minimum 95% compaction be achieved.

Possible alternative infiltration locations which are already being considered by the Project Civil Engineer would be to construct typical underground infiltration basin(s) within either or both of the two large centralized proposed landscaped courtyard areas, and/or within the proposed parking area at the southwest corner of the site. Infiltration testing was conducted within these three areas as part of this study (P-1 and P-2 are within the proposed landscaped courtyard areas, and P-4 is within the proposed southwest parking area), as well as within the currently proposed large detention/infiltration basin shown on the current plan, Plate 3 of this report (P-3 was in this area). If any of these alternative underground infiltration basin(s) are constructed, it is also recommended that a minimum of the upper 4 feet of existing native soils first be over-excavated and removed, prior to placing the first layer of infiltration system gravel within the basin(s). The bottom of these basin areas should be relatively level, prior to placing the first layer of gravel.

The intentional introduction of enormous amounts of water into the ground via the infiltration of onsite stormwater is a relatively new concept, and is inherently risky, regardless of any precautions which may be taken. Infiltration is especially risky when conducted below paved parking areas or other miscellaneous improvements, and should preferably be done below landscape areas only, and should be as far as possible from the proposed structures,

pavements, site walls, sidewalks and other improvements. Some potential settlement and cracking of any improvements located directly above, or in the vicinity of infiltration features may be possible. There should also be careful coordination of the site utility locations with any proposed stormwater infiltration features. The proposed stormwater infiltration features should *not* be allowed to come into contact with, or to even be in close proximity to utility trench backfill, and utilities are not allowed to cross above, below or through any proposed infiltration features, with the exception of irrigation lines within landscape areas entirely above infiltration areas.

5.1.9 Site Drainage

All surface runoff must be carefully controlled, and must remain a crucial element of site maintenance. Proper drainage and irrigation are important to reduce the potential for excessive infiltration adjacent to foundations, pavements, and other miscellaneous improvements. Final grading should provide positive drainage away from the proposed structures and other improvements. All pad drainage shall be collected and diverted away from proposed buildings and foundations in non-erosive devices. All drainage piping should be watertight and discharge to an appropriate location, as determined by the Project Civil Engineer.

All underground plumbing fixtures should be absolutely leak-free. As part of the maintenance program, utility lines should be checked for leaks for early detection of water infiltrating the soils that could cause detrimental soil movements. Detected leaks should be promptly repaired. Proper drainage shall also be provided away from the building footings during construction. This is especially important when construction takes place during the rainy season.

Seepage of surface irrigation water or the spread of extensive root systems into the subgrade of footings, slabs, concrete flatwork or pavements can cause differential movements and consequent distress in these structural elements. Trees and large shrubbery should *not* be planted so that roots grow under foundations and flatwork when they reach maturity. Landscaping and watering schedules should be planned with consideration for these potential problems.

Drainage systems should be well maintained, and care should be taken to *not over* or *under* irrigate the site. Landscape watering should be held to a minimum while maintaining a uniformly moist condition without allowing the soil to dry out. During extreme hot and dry periods, adequate watering may be necessary to keep soil from separating or pulling back from the foundations. Cracks in paved surfaces should be sealed to limit infiltration of surface waters.

5.1.10 Plan Review

When final Grading and Structural Plans become available, they should be reviewed by AGS *prior* to submittal to regulatory agencies for approval. Additional analysis *may* be required at that time depending on specific details of the proposed grading and improvements. Approval by this office will be indicated on the plans by either manual or digital signature and stamp.

5.1.11 Additional Recommendations

The following additional geotechnical recommendations should be incorporated into the final design, and construction plans. All such work and design should be in conformance with applicable governmental regulations or the recommendations contained herein, whichever are more restrictive. The following recommendations have *not* been reviewed or approved by any governing agency at this time. These recommendations may change based on obtaining approval from the County. Design of the proposed project should be made following approval from the County.

5.2 Site Preparation

General guidelines are presented below to provide a basis for quality control during site grading. It is recommended that all compacted fills be placed and compacted with engineering control under continuous observation and testing by a field representative of the Geotechnical Engineer, and in accordance with the following requirements.

5.2.1 Removals

a. When demolishing any existing improvements on the site, the contractor should locate any existing foundations, floor slabs, debris pits, existing fill, and subsurface trash which may be present. These soils and structures should be completely removed. In the area of the proposed structures and other improvements, deeper removals may be required, as discussed below.

b. Remove all vegetation and loose soil *prior* to fill placement. The general depth of stripping should be sufficiently deep to remove any root systems, and the upper relatively porous soils. Based on our subsurface exploration across the site, the thickness of the upper relatively porous soil requiring removal is anticipated to be approximately 2 to 3 feet, but for uniformity, the depth of initial over-excavation should be an overall minimum depth of 3 feet below the existing site grade. In addition, a careful search shall be made for subsurface trash, abandoned masonry, abandoned tanks and septic systems, and other debris during grading. All such materials shall be removed *prior* to fill placement. The removal of trees and large shrubs should include complete removal of their root structures.

c. In the area of the proposed structures, and throughout the entire site where the existing grade will be raised by the placement of additional fill, any existing artificial fill, disturbed soils and the upper relatively porous soils should be over-excavated and recompacted. For uniformity, it is recommended that this initial depth of over-excavation extend to a minimum of 3 feet below the existing site grade, and 3 feet below the bottom of the proposed building and retaining wall foundations, whichever is deeper. In addition, all building and retaining wall foundations should be underlain by a relatively uniform blanket of newly placed compacted fill, where the ratio of the maximum to minimum depths of compacted fill below bottom of footing does not exceed approximately 2.5:1.

d. In proposed street, parking, driveway, and other flatwork areas (patios, walkways, etc.), and any other areas of miscellaneous surface improvements, and where the existing grade is to be raised by the placement of fill, any existing artificial fill, disturbed soils, and upper relatively porous soils should be over-excavated and recompacted. In order to provide more uniform support for the proposed fill and overlying improvements, the depth of initial over-excavation should extend to a minimum of 3 feet below existing and future site grade, and a minimum of 12 inches below bottom of improvements or pavement structural section, whichever is deeper.

e. The lateral limits of initial over-excavation can be limited to the areas of the proposed structures, retaining walls, pavement, and other miscellaneous improvements, and areas where the grade will be raised by the placement of additional compacted fill, but should extend a distance of at least 5 feet beyond the outside perimeter of all building and retaining wall foundations where possible, or for a distance equal to the depth of compacted fill, whichever is greater. The lateral limits of over-excavation should extend a minimum distance of at least 2 feet beyond the outside perimeter of pavement areas and other surface improvements, where possible, or for a distance equal to the depth of compacted fill, whichever is greater. A careful search shall be made for deeper areas of loose soil during grading operations. If encountered, loose areas should be properly removed to the firm underlying native soil and properly compacted.

5.2.2 Bottom Stabilization

a. Depending on the time of year, amount and recency of precipitation, and the type and size of equipment utilized during grading, stabilization of the bottom of over-excavation may be required. If the bottom is found to be 'pumping' due to excessive moisture, stabilization may be required in order to allow the placement and proper compaction of fill. At the time of our

field exploration, which was conducted during a prolonged period of relatively dry weather, the upper earth materials in the areas explored had moisture contents in a range not likely to cause pumping at the depth of over-excavation. However, the soils may have increased moisture content directly below the existing trees, in the areas of the currently active orchard drip irrigation system, and/or during winter.

b. It's our recommendation that bottom stabilization, if and where required, consist of alternating layers of Tensar *InterAx* Geogrid and aggregate base. Using this method, the required over-excavation should still first be made to a minimum depth of 3 feet below the existing and future grade level, and a minimum of 3 feet below bottom of the proposed building foundations, whichever is deeper. It is recommended that a large excavator staged outside the excavation be utilized for the initial over-excavation in any areas of pumping soils. The first layer of geogrid should then be placed directly on a relatively level, native soil bottom of over-excavation. Adjacent layers of geogrid should be overlapped a minimum of 18 inches.

c. Some type of imported aggregate base material, which may include recycled AC/PCC/AB should then be placed over the geogrid in two approximately 6-inch thick compacted layers (about 8 to 9-inch +/- loose lifts), for a total of 12 inches of compacted base, compacted to a minimum 90% compaction. The imported 'base-like' material does not have to meet exact road base specifications, but should have very minimal fines content, similar to base. The intent of recommending this general type of material is that it compacts more easily than a typical soil with more fines content, thereby reducing potential disturbance to the underlying subgrade, and increasing the ease of compaction. This type of material is also less prone to absorb excessive moisture from the very moist subgrade soils that would underlie the geogrid in any areas needing stabilization, and a generally granular type of material is required for interlock with the geogrid, in order to mobilize the functionality of the geogrid.

d. It is recommended that the base be properly moisture conditioned and thoroughly mixed *outside* the excavation, and prior to placement over the geogrid. It is also recommended that an excavator staged outside the excavation, or small track-mounted equipment, be utilized to spread the base over the geogrid. Wheel-mounted equipment and dynamic compaction methods would not be recommended for compaction over pumping soils.

e. If sufficient stabilization has not yet been achieved to allow the placement and compaction of onsite soils over the top of the first 1-foot of geogrid and compacted base, then another layer of geogrid should be placed on top of the base, followed by a 6-inch layer of compacted base. Again, if sufficient stabilization has not yet been achieved, another 6-inch layer of compacted base should be placed, and stabilization tested again. If stabilization has not been achieved by this time, the use of smaller and/or track-mounted equipment should be considered for use within the excavation. If necessary, another layer of geogrid could be placed, followed by another 6-inch layer of compacted base.

5.2.3 Suitable Fill Material

a. The excavated onsite soils, cleaned of deleterious material, can be re-used for fill, but should be moisture conditioned (i.e., by drying, or adding water, as necessary), and thoroughly mixed. Rock larger than 6 inches should *not* be buried or placed in compacted fill. Rock fragments less than 6 inches may be used provided the fragments are *not* placed in concentrated pockets, and a sufficient percentage of finer grained material surrounds and infiltrates the rock voids.

b. Imported material should generally have engineering properties similar to, or more favorable that those on the subject site, and it is also recommended that any import material have an

expansion index of less than 50, and an R-value of at least 15. Imported material will require testing to verify the engineering properties, and must be approved by the Geotechnical Engineer *prior* to placement on the site.

5.2.4 *Placement of Compacted Fill*

a. All fill materials should be placed in controlled, horizontal layers *not* exceeding 6 to 8 inches in loose thickness, and moisture conditioned to a minimum of approximately 2% over optimum moisture content, but no more than approximately 5% over optimum, and *thoroughly* mixed. This recommendation for minimum moisture content is based on the expansiveness of the upper onsite soil, and could be reduced for soils with much lesser expansion potential, but it is recommended that all earth materials, including aggregate base, be moisture conditioned to at least optimum moisture content, prior to compaction.

b. Fill materials should be compacted to a minimum 90% of the laboratory maximum dry density (95% for the upper 12 inches in areas subject to vehicular traffic, and for the slopes around the proposed detention/infiltration basin), as determined by ASTM D1557. If either the relative compaction or moisture content do *not* meet these criteria, the contractor should rework the fill until it does meet the criteria. If the fill materials pump (flex) under the weight of construction equipment, difficulties in obtaining the required minimum compaction may be experienced. Therefore, if soil pumping occurs, it may be necessary to control the moisture content to a closer tolerance (e.g., 2 to 3% above optimum), use construction equipment that is not as prone to cause pumping, or implement the stabilization methods discussed previously in this report.

c. The field test methods to be used to determine the in-place dry density of the compacted fill shall be in conformance with either ASTM D1556 (sand cone test method) or ASTM D2922 (nuclear gauge method).

d. Subgrade to be utilized for the support of any exterior surface improvements shall be moisture conditioned, as required, to at least approximately 2% over optimum moisture content, but no more than approximately 5% over optimum, thoroughly mixed, and be recompacted to at least 90% of the maximum dry density to a depth of at least 12 inches (95% for the upper 12 inches in areas subject to vehicular traffic). This recommendation for minimum moisture content is based on the expansiveness of the onsite soil, and could be reduced for soils with lesser expansion potential, but it is recommended that all earth materials, including aggregate base, be moisture conditioned to at least optimum moisture content.

5.2.5 *Fill Slopes*

a. Fill slopes must be founded on a keyway of undisturbed, competent native material approved by the Geotechnical Engineer or Geologist, and/or their field representative. The keyway should be a minimum of 10 feet in width, dipped into the retained side, must extend at least to the proposed toe of slope, and extend at least 3 feet into competent native material at the outer edge of the keyway. The fill slope should be benched into competent, native material.

b. Fill slopes shall be constructed by placing fill soil to a sufficient distance beyond the proposed finished slope surface to allow compaction equipment to operate at the outer surface limits of the final slope surface, and then cutting back to finished grade. Other suitable methods of properly compacting the slope surface would be allowed along property lines.

5.2.6 *Testing of Compacted Fill*

a. At least one compaction test shall be performed for every 500 yd^3 of the fill material. In addition, at least one test shall be performed for every 2 feet of fill thickness.

5.2.7 ***Detention/Infiltration Basins***

a. If the large detention/infiltration basin shown near the west end of the site is to be constructed as shown on the attached Plate 2 of this report, a minimum of approximately the upper 4 feet of existing native soils should first be over-excavated and removed, prior to placing select, primarily granular, and relatively permeable compacted fill for the bottom of the basin. It is also recommended that the contact between the bottom of the imported primarily granular fill and underlying native soils be relatively level.

b. The select imported primarily granular basin bottom fill material *would* still require the typical minimum 90% relative compaction, in order to maintain the stability of this basin and adjacent slopes, and therefore this material, *when compacted*, will have to be at least as permeable as the underlying native soils, by extensive testing throughout the placement of this fill.

c. The sloping sides within the interior of the basin should be lined with an impermeable liner, to prevent the migration of the detained water towards the descending perimeter slopes, and also to prevent erosion of the interior slopes. The liner should also extend vertically downward from the toe of the interior descending slopes, to the bottom of the permeable import material (the contact with undisturbed native soils), in order to prevent or at least reduce horizontal migration of the detained water towards the exterior slope faces, and reduce the potential that infiltrated water would daylight in the lower surrounding areas to the north and west of the basin. The descending slopes around the perimeter of this proposed detention/infiltration basin should be compacted to a minimum 95% relative compaction, and the earth materials utilized to construct these slopes be relatively cohesive.

d. If any of the three alternative infiltration basin(s) are to be constructed, it is recommended that the upper 4 feet of existing native soils in these areas first be over-excavated and removed, prior to placing the first layer of infiltration system gravel within the basin(s). The bottom of these basin(s) should be relatively level, prior to placing the first layer of gravel. Additional gravel may be utilized as necessary to fill up to the bottom of proposed infiltration chambers.

5.2.8 ***Inclement Weather and Construction Delays***

a. If construction delays or the weather result in the surface of the fill drying, the surface should be scarified, moisture conditioned and recompacted before the next layer of fill is added. Each new layer of fill should be placed on a rough surface so planes of weakness are not created in the fill.

b. During periods of wet weather and before stopping work, all loose material shall be spread and compacted, surfaces shall be sloped to drain to areas where water can be removed, and erosion protection or drainage provisions shall be made in accordance with the plans provided by the Civil Engineer. After the rainy period, a field representative of the Geotechnical Engineer shall *review* the site for authorization to resume grading, and to provide any specific recommendations that may be required. As a minimum, however, surface materials previously compacted before the wet weather shall be scarified, brought to the proper moisture content, and recompacted *prior* to placing additional fill.

c. During the construction of foundations, floor slabs and any exterior concrete flatwork, construction sequences should be scheduled to reduce the time interval between subgrade preparation and concrete placement to avoid drying and cracking of the subgrade, or the surface should be covered or periodically wetted to prevent drying and cracking.

5.2.9 Responsibilities

a. Representative samples of material to be used as compacted fill should be analyzed in the laboratory by the Geotechnical Engineer to determine the physical properties of the materials. If any materials other than those previously tested are encountered during grading, the appropriate analysis of this material should be conducted by the Geotechnical Engineer as soon as practicable. Any imported soil from off-site sources shall be approved *prior* to placement.

b. All grading work shall be observed and tested by the Project Geotechnical Engineer or their field representative to confirm proper site preparation, excavation, scarification, and compaction of onsite soil, selection of satisfactory fill materials, and placement and compaction of fill. All removal areas and footing excavations shall be observed by the field representative of the Project Geotechnical Engineer before any fill or steel is placed.

c. The lateral limits and the depths of the required over-excavation and recompaction should be shown by the Civil Engineer on the grading plans.

d. The grading contractor has the ultimate responsibility to achieve uniform compaction in accordance with the geotechnical report and grading specifications.

5.3 Utility Trench Backfill

The onsite soils are suitable for backfill of utility trenches from 1-foot above the top of the pipe to the surface, provided the material is free of organic matter and deleterious substances. The existing site soils should provide a firm foundation for site utilities, but any soft or unstable material encountered at pipe invert should be removed and replaced with an adequate bedding material.

The site Civil Engineer in accordance with manufacturer's requirements should specify the type of bedding materials. Granular soils should be imported for bedding and shading of utilities. Jetting of bedding materials should *not* be permitted unless appropriate drainage is provided and the bedding has a sand equivalent greater than 50.

Trench backfill should be placed in 6 to 8-inch lifts, and properly moisture conditioned and compacted in accordance with the recommendations provided in the *Site Preparation* section of this report. Jetting of trench backfill is *not* acceptable to compact the backfill.

Major underground utilities shall *not* cross beneath buildings unless specifically approved by the Project Civil Engineer and respective utility company. If approved, trenches crossing building areas shall be backfilled with a select gravelly sand compacted to 95% relative compaction.

5.4 Temporary Excavations

It is anticipated that most temporary excavations may be made to a maximum vertical height of 5 feet, however any sands which may be encountered should be excavated at a uniform 1.5:1 gradient. Excavations greater than 5 feet in height should be sloped back at either a uniform 1:1 gradient for cohesive soils, and 1.5:1 for sands. Excavations should *not* be allowed to become soaked with water or to dry out. Surcharge loads should *not* be permitted within a horizontal distance equal to the height of the excavation from the top of the excavation, unless the excavation is properly shored. Excavations that might extend below an imaginary plane inclined at 45 degrees below the edge of an existing foundation should be properly shored to maintain foundation support for the existing structure. All temporary excavation should be observed by a representative of the Geotechnical Engineer during excavation, to verify the anticipated soil conditions.

5.5 Foundation Design

After the over-excavation and recompaction of the existing upper site soils, and the import and placement of additional compacted fill to achieve the future finished grades across the site, conventional shallow footings founded entirely within certified compacted fill can be utilized for foundation support for the proposed multi-family structures, and retaining walls. All foundations for these structures should be underlain by a minimum of 3 feet of compacted fill. Free-standing site walls not exceeding approximately 6 feet in height may bear in either compacted fill, or undisturbed, competent native soils, although any given length of wall should bear entirely within one material. The following design criteria may be used in the design of conventional, shallow footings.

5.5.1 Minimum Footing Dimensions

Minimum Footing Embedment Depth (inches)	Minimum Continuous Footing Width (inches)	Minimum Isolated or Pad Footing Width, (inches)
1 or 2-Story - 21 3-Story - 24	1-Story – 12 2-Story – 15 3-Story - 18	24

Where located adjacent to utility trenches, footings shall extend below a 1:1 plane projected upward from the inside bottom of the trench. Note that these foundation depths are based on the expansiveness of the upper onsite soils. If less expansive soils are placed *throughout* the upper 4 feet of any given building pad, retaining wall area, or other miscellaneous footing areas, these values could be reduced, but should still comply with the minimum depths provided in Ventura County Building and Safety Standard B-49, Table 1805.4.2.

5.5.2 Allowable Bearing Pressure and Lateral Resistance

Allowable net vertical soil bearing pressure, including dead and live loads, are given below for footings founded on compacted fill at the minimum required embedment depths, provided the footing width equals or exceeds the recommended minimum.

Structure Type	Bearing Material	Allowable Bearing Pressure (psf)	Allowable Sliding Friction Coefficient	Allowable Passive Resistance (psf/ft of depth)	Maximum Passive Resistance (psf)
BUILDINGS & RETAINING WALLS	COMPACTED FILL	2500	0.3	250	2500
FREE-STANDING SITE WALLS <~6'	COMPETENT NATIVE SOILS	1000	0.2	150	1500

The bearing capacity can be increased by ⅓ when considering short duration wind or seismic loads. Resistance to lateral loads can be assumed to be provided by friction along the base of the foundation, and by passive earth pressure on the side of the footing. The allowable friction coefficient may be used with the vertical dead loads, and the allowable lateral passive pressure can be utilized for the sides of footings poured against the recommended bearing material. These allowable values can be increased by a factor of 1.5 to convert from allowable to ultimate values. It is recommended that the upper 1-foot of soil be neglected when computing lateral resistance, due to the potential for the material to become disturbed or degraded during the life of the structure.

5.5.3 Foundation Settlement

Static settlement of proposed foundations due to dead and frequently applied live loads is not expected to exceed approximately ½ to ¾-inch under the assumed loading conditions, and is expected to occur primarily upon initial application of loading. Differential settlement is not expected to exceed approximately ¼ to ½-inch.

5.5.4 Steel Reinforcement

All continuous foundations should be reinforced with a minimum of four #4 steel bars. Two of these should be placed near the top of the foundation, and two should be placed near the bottom. Final structural details of the

footings, such as footing thickness, concrete strength, and amount of reinforcement, should be determined by the project Structural Engineer, but should comply with the above minimums. The earth materials underlying the subject site are in the *low to medium* expansion range. Expansion index tests should be performed at the time of grading, to determine the final expansion index of the graded pads.

5.5.5 Required Observations

Prior to placing concrete in the footing excavations, an observation should be made by the field representative of the Geotechnical Engineer, to confirm that the footing excavations are free of loose and disturbed soils, and are embedded in the recommended earth materials.

5.6 Floor Slab Design

It is recommended that concrete slabs-on-grade be a minimum of 4 inches thick, and be reinforced with a minimum of #4 steel bars placed a minimum of 18 inches on center each way. The exact structural details such as slab thickness, concrete strength, reinforcement, and joint spacing, should be determined by the project Structural Engineer, but should comply with these minimum requirements. Additional expansion index testing should be performed at the time of grading to confirm the expansion index of the final graded pads.

Cracking of concrete flatwork can occur and is relatively common. Steel reinforcement and crack control joints are intended to reduce the risk of concrete slab cracking, as are the use of proper concrete curing, and sometimes fiber reinforced concrete. Also, concrete slabs are generally not perfectly level, but they should be within tolerances included in the project specifications.

Tile flooring can crack, reflecting cracks in the underlying concrete slab. Therefore, if tile flooring is used, the slab designer should consider additional steel reinforcement, above minimum requirements, in the design of concrete slabs-on-grade where tile will be installed. Furthermore, the tile installer should consider installation methods, such as using a vinyl crack isolation membrane between the tile and concrete slab, to reduce the potential for tile cracking.

If earthwork operations are conducted such that the construction sequence is not continuous, or if construction operations disturb the surface soils, it is recommended that the exposed subgrade to support concrete slabs be tested within a day of the concrete pour or placement of sand (or vapor barrier, where utilized) to verify adequate compaction and moisture conditions. If adequate compaction and moisture conditions are not demonstrated, the disturbed subgrade should be over-excavated, scarified, and recompacted in accordance with the guidelines in the *Site Preparation* section of this report *prior* to the slab being poured, or sand and vapor barrier being placed.

5.6.1 Sand and Vapor Barrier

It is recommended that all building floor slabs be underlain by a *minimum* of 4 inches of sand, based on the expansion index range of the onsite soils, and County of Ventura requirements. If soils in the *very low* expansion range are placed *throughout* the upper 4 feet of any given building pad, 2 inches of sand could be utilized. The thickness of sand should comply with the thickness provided in Ventura County Building and Safety Standard B-49, Table 1805.4.2. It is also recommended that a minimum 15-mil thick plastic vapor barrier be used under floor slabs in moisture sensitive areas. The vapor barrier should be installed in accordance with the recommendations contained in the latest version of ASTM E1643.

The literature is mixed regarding the preferred placement of the vapor barrier with respect to the sand and concrete slab. Some designers prefer to place the vapor directly below the concrete slab, and some prefer to sandwich the vapor barrier between layers of sand. It is our opinion, and the opinion of the *California Geotechnical Engineering Association* that the decision of where to place the vapor barrier does not fall under the responsibility or expertise of the Geotechnical Engineer, and we will therefore defer to the project designer on this matter. Appropriate precautions should be taken whichever placement is chosen.

Seams of the vapor barrier should be overlapped and sealed. Where pipes extend through the vapor barrier, the barrier should be sealed to the pipes. Tears or punctures in the vapor barrier should be completely repaired *prior* to placement of concrete. The concrete mix should be designed so as to minimize possible curling of the slab. The concrete slab should be allowed to cure properly before placing vinyl or other moisture-sensitive floor covering.

5.7 Asphalt and Concrete Pavement

5.7.1 Grading

All exterior areas to be paved with asphalt or concrete should be graded in accordance with the general recommendations for site grading as described in the *Site Preparation* section of this report. In proposed parking and driveway areas, and any other exterior flatwork areas (walkways, patios, etc.), any existing fill material, loose or disturbed soils, and relatively porous upper site soils should be over-excavated and recompacted. The depth of over-excavation should extend to a minimum of 3 feet below the current existing site grade, or 12 inches below future subgrade level, whichever is deeper, and a minimum of 12 inches below the bottom of future concrete, asphalt or aggregate base section. If test results show that proper moisture and compaction requirements do not exist just *prior* to placing base or placing pavements, the surface should be scarified, moisture conditioned, and properly recompacted.

Compaction tests will be required for all asphalt and aggregate base. A minimum relative compaction of 95% is required for all asphalt, aggregate base, and upper 12 inches of subgrade soils. The aggregate base should have a minimum *R*-value of 78 and meet recognized industry specifications for aggregate base. Base materials should be placed and compacted in lifts not exceeding 6 inches. Asphalt should *not* be placed if the base is pumping. Base materials are *not* required beneath curbs and gutters, however, if base materials are not utilized beneath the curbs and gutters, it is recommended that the subgrade soils be recompacted to at least 95% relative compaction to a minimum depth of 12 inches below the bottom of curbs and gutters.

5.7.2 Maintenance

Pavement section design assumes that proper maintenance practices, such as sealing and repair of localized areas of distress, are employed throughout the design life of the pavement.

5.7.3 Asphalt Pavement Design

Pavement section calculations were performed for asphalt pavement design for a range in traffic indices. Selection of the appropriate traffic index to use should be made by the Project Civil Engineer based on their knowledge of traffic flow and loadings.

The structural sections for asphalt pavement were computed in general accordance with the Caltrans method (**California Department of Transportation Highway Design Manual**), using a design R-value of 10, based on the results of R-value testing of a representative sample of the upper onsite soils. The results of the R-value testing are included in Appendix B of this report, and recommended pavement sections are summarized in the following table. Note that the City of Ventura may have overriding minimum pavement sections for public streets.

Traffic Index	Thickness (inches)	
	Asphalt	Aggregate Base
5.0	4.0	6.5
6.0	4.0	10.5
7.0	4.0	12.5

5.7.4 Confirmation of R-Value

Additional representative testing to determine the R-value of the subgrade soils in street, parking and driveway areas, should be performed near or after the completion of grading, in order to finalize the pavement section. It should be noted that the pavement section design recommendations presented in this report may change, depending

on the final composition of the subgrade soils. More favorable pavement sections could be utilized if the upper 2 feet of subgrade soils in proposed asphalt pavement areas are constructed utilizing imported soils with an R-value which is *uniformly* and substantially greater than 10.

5.7.5 Concrete Pavement Design

It is recommended that all concrete pavement subject to vehicular traffic be a minimum of 8 inches thick, and be underlain by a minimum of 6 inches of aggregate base. Concrete flatwork subject only to pedestrian traffic (i.e., sidewalks, walkways, patios, etc.) should be a minimum of 5 inches thick, and need not be underlain by aggregate base. All exterior concrete should be reinforced with a minimum of #4 steel bars placed on 18-inch centers each way. Note that the City of Ventura may have overriding minimum concrete sections and reinforcement for public streets and sidewalks.

It is also recommended that the perimeter of all concrete flatwork and hardscape areas have a reinforced, thickened edge, a minimum of 8 inches wide, and extending a minimum of 8 inches below the bottom of the concrete flatwork, and 12 inches below adjacent grade. The purpose of the thickened edge is to reduce the migration of moisture to or from the area below the slab, thereby reducing the amount of moisture fluctuation below the slab, reducing shrinking and swelling and the consequent movement and distress. The use of permeable pavers or any system of un-grouted bricks or pavers is not recommended, due to the potential for increased water penetration and expansive soil movement. These recommendations could be modified if less expansive soils are imported, and are uniformly present within the upper 2 to 3 feet of final subgrade in any given proposed flatwork or pavement area, depending on the type and use of the pavement/flatwork.

Cracking of exterior concrete and other hardscape can occur and is relatively common. Areas underlain by expansive soils are especially prone to movement and cracking. Steel reinforcement, crack control joints and deepened edges are intended to reduce the risk of concrete cracking, as are the use of fiber reinforced concrete and proper concrete curing. The location and severity of concrete cracking can be controlled and reduced through the use of proper jointing and other construction practices, but can never be completely eliminated.

5.8 Retaining Wall Design Criteria

The following retaining wall design information may be utilized in the design of site retaining walls. Retaining wall foundations may be designed utilizing the criteria provided in the *Foundation Design* section of this report.

5.8.1 Static Lateral Earth Pressures

The earth pressure behind retaining walls depends on the allowable wall movement, type of backfill materials, backfill slopes, surcharges, and hydrostatic pressures if any. The following equivalent fluid pressures are recommended for vertical walls with no hydrostatic pressure, no surcharge, no seismic effects, and a backfill slope with a gradient less (flatter) than 5(H):1(V). Seismic lateral forces would be in addition to the static wall pressures provided below, and would be required for walls retaining more than 6 feet.

	Equivalent Fluid Unit Weight (pcf)			
Wall Movement	Clean Sand or Gravel Backfill (GW, GP, SW, SP)	Silty Sand or Silty Gravel Backfill (SM, GM)	Clayey Sand, Clayey Gravel Backfill (SC, GC)	Silts, Clays (ML, CL)
FREE TO DEFLECT	30	40	45	55
RESTRAINED	40	50	60	80

In areas where the retaining walls retain sloping ground steeper than 5(H):1(V), the equivalent unit weights in the above table should be increased by 13 pcf, for gradients up to the maximum allowable of 2(H):1(V).

These values are applicable for backfill placed between the wall stem and an imaginary plane rising at a 45-degree angle from below the edge (heel) of the wall footing. If the onsite soil is used as backfill within this zone, or is

otherwise present within this zone, the equivalent fluid unit weight associated with a soil classification of ML/CL should be used.

The surcharging effect of anticipated adjacent loads on the wall backfill due to traffic, footings, or other loads, should be included in the wall design. The magnitude of lateral load due to surcharging depends on the magnitude of the surcharge, the size of the surcharge-loaded area, and the distance of the surcharge from the wall. We can provide assistance in evaluating the effects of surcharge loading, if desired, once details are known and provided.

5.8.2 Seismic Lateral Earth Pressures

In accordance with the requirements of the 2019 California Building Code, seismic lateral force should be incorporated into the design of all retaining walls retaining more than 6 feet of earth materials. A seismic lateral force of $15.9H^2$ pounds per lineal foot of wall should be added to *cantilevered* walls retaining more than 6 feet of earth materials and level ground, and a seismic lateral force of 26.6H2 pounds per lineal foot of wall should be added to *cantilevered* walls retaining more than 6 feet of earth materials, and sloping ground up to a maximum 2:1 gradient, where H is the retained height, in feet. A seismic lateral force of $25.8H^2$ pounds per lineal foot of wall should be added to *restrained* walls retaining more than 6 feet of earth materials, and level ground, where H is the retained height, in feet. The seismic force should be applied at a height of 0.4H above the bottom of the wall, and would be in addition to the static lateral earth pressures given in the previous section.

5.8.3 Backfill and Drainage

Except for the upper 18 to 24 inches, the soil immediately adjacent to backfilled retaining walls should be free-draining filter material (such as Caltrans Class 2 permeable material), or gravel wrapped in filter fabric, within a minimum horizontal distance of 1-foot from the back face of the wall. As an alternative to either one of these, a drainage tile product such as Miradrain may be applied to the back face of wall, over the waterproofing. Weep holes and/or a subdrain pipe, as appropriate, should be installed at the base of retaining walls. Subdrain pipe should consist of a minimum 4-inch diameter perforated PVC pipe meeting ASTM D2729 or better, surrounded by a minimum of 1 cubic foot of gravel per lineal foot of pipe, and the entire pipe and gravel system should be wrapped in filter fabric, such as Mirafi 140N. Accordion or similar type pipe is *not* acceptable for subdrain pipe. The top 18 to 24 inches should be backfilled with less permeable compacted fill to reduce infiltration. Figure 7 provides a *Typical Retaining Wall Drainage Detail.*

It is recommended that all retaining walls be properly waterproofed. Advanced Geotechnical Services does not practice in the field of waterproofing design, or the inspection of its application.

During grading and backfilling operations adjacent to any wall, heavy equipment should not be allowed to operate within 5 feet laterally of the wall or within a lateral distance equal to the wall height, whichever is greater, to avoid developing excessive lateral pressures. Within this zone, only hand-operated equipment should be used to compact the backfill soils.

6. OBSERVATIONS AND TESTING

Prior to the start of site preparation and/or construction, *it is recommended that a meeting be held with the Contractor to discuss the project.* We recommend that AGS be retained to perform the following tasks prior to, and/or during construction. Please *advise* AGS a minimum 24 hours *prior* to any required site visit. *All approved plans, permits, and geotechnical reports must be at the jobsite and be made available during inspections.*

a. *Review* grading, foundation, and drainage plans to *verify* that the recommendations contained in this report have been properly interpreted and are incorporated into the project specifications. *If we are not accorded the opportunity to review these documents, we can take no responsibility for misinterpretation of our conclusions and recommendations.*

b. *Observe and advise* during all grading activities, including site preparation, foundation and retaining wall excavation, and placement of fill, to *confirm* that suitable fill soils are placed upon competent material, and to allow design changes if subsurface conditions differ from those anticipated, *prior* to the start of construction.

c. *Observe* the installation of all drainage devices.

d. *Test* all fill placed for engineering purposes to *confirm* that suitable fill materials are used and properly compacted.

7. LIMITS AND LIABILITY

All building sites are subject to elements of risk that cannot be wholly identified and/or entirely eliminated. Building sites are subject to many detrimental geotechnical hazards, including but *not* limited to the effects of water infiltration, erosion, concentrated drainage, total settlement, differential settlement, expansive soil movement, seismic shaking, fault rupture, landsliding, and slope creep. The risks from these hazards can be reduced by employing subsurface exploration, laboratory testing, analyses, and experienced geotechnical judgment. Many geotechnical hazards, however, are highly dependent on the property owner properly maintaining the site, drainage facilities, and slope and by correcting any deficiencies found during occupancy of the property in a timely manner. Even with a thorough subsurface exploration and testing program, significant variability between test locations and between sample intervals may exist. Ultimately, geotechnical recommendations are based on the experience and judgment of the geotechnical professionals in evaluating the available data from site observations, subsurface exploration, and laboratory tests. Latent defects can be concealed by earth materials, deposition, geologic history, and existing improvements. If such defects are present, they are beyond the evaluation of the geotechnical professionals. No warranty, expressed or implied, is made or intended in connection with this report, by furnishing of this report, or by any other oral or written statement. Owners and developers are responsible for retaining appropriate design professionals and qualified contractors in developing their property and for properly maintaining the property. Retaining the services of a geotechnical consultant should *not* be construed to relieve the Owner, Developer, or Contractors of their responsibilities or liabilities.

The analysis and recommendations submitted in this report are based in part on our subsurface exploration, laboratory testing, site observations, and provided data on geology and the proposed site development. Our descriptions and the boring logs may show distinctions between fill and native soils, between native (e.g., alluvium, colluvium, slopewash) and bedrock formation, and between soil type (e.g., sands and silty sands). Such distinctions were based on geologic information, grading plans when available, intermittent recovered soil/bedrock samples, and judgment. Delineations between these categories of materials may not be perfect and may be subject to change as more information becomes available. For example, judgments may be clouded when recovered samples are intermittent and small in comparison to the volume of soil under study, and macrostructure that would aid the identification process are not as apparent as they would be when the borehole is geologically downhole logged by entering the excavation. When the age of the fill is old, the difference between the structure of the fill and native materials may be less pronounced, or the degree of bedrock formation weathering sometimes makes it difficult to distinguish between overlying alluvium, colluvium, or slopewash and weathered bedrock formational material. In general, our recommendations are based more on the properties of the materials than on the category of the material type such as fill, alluvium, colluvium, slopewash, or bedrock formation. Furthermore, the actual stratigraphy may be more variable than shown on the logs.

Although this report may comment on or discuss construction techniques or procedures for the design engineer's guidance, this report should *not* be interpreted to prescribe or dictate construction procedures or to relieve the contractor in any way of their responsibility for the construction.
Please be aware that the contract fee for our services to prepare this report does not include additional work that may be required, such as grading observation and testing, footing observations, plan review, or responses to governmental (regulatory) plan reviews associated with you obtaining a building permit. Where additional services

are requested or required, you will be billed for any equipment costs and on an hourly basis for consultation or analysis.

The Geotechnical Engineer's actual scope of work during construction is very limited and does *not* assume the day-to-day physical direction of the work, minute examination of the elements, or responsibility for the safety of the contractor's workers. Our scope of services during construction consists of taking soil tests and making visual observations, sometimes on only an intermittent basis, relating to earthwork or foundation excavations for the project. We do *not* guarantee the contractor's performance, but rather look for general conformance to the intent of the plans and geotechnical report. Any discrepancy noted by us regarding earthwork or foundations will be referred to the Owner, project Engineer, Architect, or Contractor for action.

This report is issued with the understanding that it is the responsibility of the Owner, or of their representative, to ensure that the information and recommendations contained herein are called to the attention of the Architect and Engineers for the project and incorporated into the plan and that the necessary steps are taken to see that the Contractor carry out such recommendations in the field. Advanced Geotechnical Services, Inc., (AGS) has prepared this report for the exclusive use of the Client and authorized agents, and this report should *not* be considered transferable. We do recommend, however, that the report be given to future property Owners for the sole purpose of disclosing the report findings.

Findings of this report are valid as of the date of issuance. Changes in conditions of a property may occur with the passage of time whether attributable to natural processes or works of man on this or adjacent properties. Furthermore, changes in applicable or appropriate standards occur due, for example, to legislation and broadening of knowledge. Accordingly, findings of this report may be invalidated wholly or partially by changes outside our control. Therefore, *this report is subject to our review and remains valid for a maximum period of one year*, unless we issue a written opinion of its continued applicability thereafter.

In the event that any changes in the nature and design (including structural loadings different from those anticipated), or other improvements are planned, the conclusions and recommendations contained in this report shall *not* be considered valid unless the changes are reviewed and conclusions of this report modified or verified in writing.

This report may be subject to review by controlling agencies, and any modifications they deem necessary should be made a part thereof, subject to our technical acceptance of such modifications. All submissions of this report should be in its entirety. Under no circumstances should this report be summarized and synthesized to be quoted out of context for any purpose.

Test findings and statements of professional opinion do *not* constitute a guarantee or warranty, and *no* warranties, either expressed or implied, are made as to the professional advice provided under the terms of this agreement. We have strived, however, to provide our services in accordance with generally accepted geotechnical engineering practices in this community at the time of this report.

excavated at the toe of the slope, and may not be indicative of the actual strength values of the materials which compose the slope, the inaccessible upper portion of which has been observed to be composed of resistant conglomeratic deposits.

Surficial Stability

A surficial stability analysis was performed for the slope which ascends to the east of the subject site. The slope face has been observed and mapped as exposing bedrock materials of the Pico Formation in the upper ranges of the slope, which are mantled by landslide debris, derived from the underlying bedrock, in the lower ranges of the slope.

As the majority of the upper portions of the slope face are observed to have a limited soil thickness, an assumed average soil thickness value of 5-feet was used in our evaluation. A maximum slope angle of approximately 30 degrees has been represented where the landslide debris are present, as detailed on *Cross-Section D-D'*, and this value was used in our evaluation. The material strengths of the materials evaluated in this surficial evaluation are presented in the table in the *Material Strengths* section above.

Our analyses determined that factor of safety values of equal to or greater than 1.5 for static conditions and greater than 1.1 for seismic conditions exist upon the east ascending slope under the interpreted conditions. The output file of this analysis is presented in Appendix A.

Surficial Slope Stability Factors of Safety Summary

Slope Angle	Soil Thickness	Seismic Conditions	Factor of Safety
30 Degrees	5 Feet	Static	1.5
30 Degrees	5 Feet	Seismic Acceleration = 0.196g Horizontal	1.27

Comment 5:
Please provide contour labels for the existing contour lines within the development on the grading plan.

Response 5:
Acknowledged, this has been addressed on the proposed grading plan by the project civil engineer, a copy of which has been utilized as the base map for the *Proposed Site Plan* included as Plate 1 of this response report.

Comment 6:
Additional comments may be provided upon submittal of above information.

Response 6:
Acknowledged.

Stormwater Program Comments

Comment 1:
The submitted documents did not appear to explicitly indicate the total area to be disturbed for construction and the proposed amount of impervious surface, as defined by the TGM.

Response 1:
Acknowledged, to be addressed by others.

Comment 2:
It is noted that the submitted Geotechnical Engineering Study did appear to include infiltration testing results; however, infiltration testing was completed to only four feet below the existing ground surface. The TGM requires infiltration testing 11 feet below the invert of a proposed infiltration BMP. As the applicant appears to propose an

underground BMP, it is assumed that the infiltration testing did not meet the requirements of the TGM. The infiltration safety factor worksheet may be reviewed to account for uncertainty in infiltration rates.

Response 2:
As a part of this response report, additional field infiltration testing was performed in the location of the proposed retention feature to be constructed in the western portion of the property. It is our understanding, based upon communication with the project civil engineer, that the proposed retention feature will consist of a basin to be bottomed at a depth of up to 3-feet below the existing grade.

This additional testing was performed in accordance with the specifications for the falling-head borehole infiltration test method specified in section C.6 of Appendix C of the **Ventura County Technical Manual for Stormwater Quality Control Measures, Manual Errata Update June 2018** (Geosyntec Inc. and Larry Walker Associates 2018). Our additional infiltration testing program consisted of:

a. Drilling, sampling, and logging of six infiltration test borings on August 8, 2023 (Borings PB-1 through PB-6) within the location of the proposed retention feature to be constructed in the western portion of the property. The additional infiltration test locations are shown on Plates 1 and 2 of this response report. The borings were excavated to depths of 3 feet and 14 feet below the existing ground surface with a truck mounted hollow stem auger drill rig for the purpose of evaluating the subsurface soil conditions, and to perform the additional infiltration testing. The earth materials encountered and tested are considered to be representative of the earth materials underlying the site in the vicinity of the areas tested, at the depths tested.

b. Performing field testing to determine the infiltration capabilities of the subsurface materials in below the proposed retention feature.

c. Evaluating and summarizing the infiltration test data as presented in the following paragraphs of this response.

The falling head borehole infiltration test method used consisted of the excavation of the infiltration test holes utilizing a truck mounted hollow stem auger drill rig equipped with an 8-inch diameter auger. The test holes were excavated to the anticipated depth of the bottom of the retention feature, which the project civil engineer informed us will be at approximately 3 feet below the existing grade, and to 11 feet below the anticipated bottom of the proposed retention feature, which is 14 feet below the existing grade. These testing depths are in accordance with the standards detailed in Appendix C of the **Ventura County Technical Manual for Stormwater Quality Control Measures, Manual Errata Update 2018** (Geosyntec Inc. and Larry Walker Associates 2018).

Within each of the infiltration test borings, older alluvium materials were encountered, consisting of clayey silty sand near the existing ground surface to a depth of approximately 12 to 12.5 feet, below which sandy silt materials are present. These materials were observed to be present in a generally slightly moist to moist and dense / stiff condition. Neither groundwater nor seepage were encountered within any of the infiltration test borings. More detailed descriptions of the materials encountered are presented on the Boring Logs included in Appendix A of this response report.

Upon completion of the excavation and sampling operations, each test hole was prepared by installing an appropriate length of 3-inch diameter perforated PVC pipe surrounded by crushed gravel. Twenty-four hours prior to the initiation of the infiltration testing program, each test hole was pre-saturated by filling each hole with water to near the top of the boring excavation.

At the completion of the pre-saturation period, each of the borings were observed to have completely drained. Each test hole was then refilled with water to a height of at least 12-inches above the bottom of the excavation. The water

drop in each test hole was then recorded at 30-minute intervals for a period of 4 hours, and additional water was added to the test hole to restore the top of the water column to a height of approximately 12-inches above the bottom of the boring after each reading. This process was continued for a period of 4 hours for each test boring.

The field infiltration test data is presented on Figures 1 through 3 in Appendix A of this report, and a summary of the field and corrected infiltration test results is presented in the following table, along with the appropriate correction factors and corrected rates, based on the correction factor methodology defined for the "Boring Percolation Test Procedure" on page 8 in the Los Angeles County *Guidelines for Design, Investigation, and Reporting Low Impact Development Stormwater Infiltration* document GS200.1 (Released June 30, 2014). The slowest infiltration rate obtained in each test hole was utilized in these calculations:

Test Hole	Tested Depth (feet)	Stabilized Field Infiltration Rate (minutes/inch)	Stabilized Field Infiltration Rate (inches/hour)	Correction Factor, Per LA County Document GS200.1	Corrected Infiltration Rate (minutes/inch)	Corrected Field Infiltration Rate (inches/hour)
PB-1	14	40	1.5	3.94	157.5	0.38
PB-2	3	18.5	3.25	3.69	68.1	0.88
PB-3	14	48	1.25	4.16	199.5	0.30
PB-4	3	20	3	3.88	77.5	0.77
PB-5	14	34.3	1.75	3.81	130.7	0.46
PB-6	3	15	4	3.63	54.4	1.10

Upon completion of the field testing program, the perforated pipe was removed and the test holes were backfilled with the excavated soil.

It should be noted that due to the depositional environment in which the native earth materials present below the site were deposited, the composition of the materials is somewhat variable with location and depth, and the deposited materials are complexly interbedded. Relatively small changes in grain size and fines content can have a relatively large impact on the soil permeability, as can other factors. As a result, the rates of infiltration as recorded and reported within this response report and our previously published report prepared for the site have been documented to be variable, as should be anticipated. Although lower than previously reported infiltration rates have been recorded, it should be anticipated that non-vertical flow at various depths will be a major contributor to the transport of subsurface water below the site. Additionally, it is worth noting that the testing performed previously was conducted within a 12-inch wide by 12-inch long by 12-inch deep excavation, as opposed to an 8-inch diameter boring, which may additionally account for the variability in reported infiltration rates.

Comment 3:
The submitted conceptual site plans did not appear to identify drainage areas and impervious areas.

Response 3:
Acknowledged, to be addressed by others.

Comment 4:
A PCSMP (i.e., PCSMP output from the applicable sections of the TGM Tool) was not submitted for review.

Response 4:
Acknowledged, to be addressed by others.

Comment 5:
The submitted documents did not appear to indicate the pretreatment proposed for the infiltration BMP.

1 Project Description and Impact Summary

1.1 Introduction

This study analyzes the potential noise and vibration impacts of the proposed Ventura Ranch Farmworker Housing Complex (herein referred to as "proposed project" or "project") located in unincorporated Ventura County, California. Rincon Consultants, Inc. (Rincon) prepared this study under contract to the County of Ventura to use in support of the environmental documentation being prepared pursuant to the California Environmental Quality Act (CEQA). The purpose of this study is to analyze the project's noise and vibration impacts related to both temporary construction activity and long-term operation of the project. Table 1 provides a summary of impacts associated with the construction and implementation of the proposed project.

Table 1 Summary of Impacts

Issue	Finding	Applicable Recommendations
Issue 1: Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.	Less Than Significant Impact	None
Issue 2: Generation of excessive ground-borne vibration or ground-borne noise levels.	Less Than Significant Impact	None
Issue 3: For a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels.	No Impact	None
Issue 4: Would the project conflict with land use compatibility guidelines for noise?	No Conflict	None

1.2 Project Location

The approximately 83-acre project site is located at 4884 North Ventura Avenue (Assessor's Parcel Numbers [APNs] 063-0-110-065, -035, -090, and -145), east of Ventura Avenue and Floral Drive, in unincorporated Ventura County. The project site is located 3.62 miles north of the City of Ventura and is within the City's sphere of influence. The project site currently contains undeveloped open space, an orchard with associated accessory structures (e.g., barns and storage), and a single-family residence with a covered patio and detached garage. Single-family residential uses and open space are located to the north, with undeveloped open space to the east, single-family and agricultural uses to the south, and Highway 33 to the west, across from which is vacant industrial land. Additionally, the project site surrounds a water storage facility, which is not part of the project site. Figure 1 shows the projects' regional location, and Figure 2 shows the project vicinity.

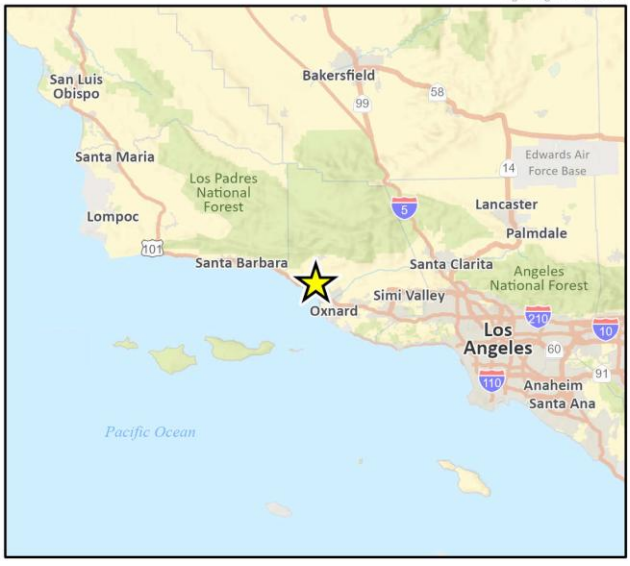

Figure 2 Project -Vicinity

1.3 General Plan Designation

According to the Ventura County 2040 General Plan, the project site has a General Plan land use designation of Open Space (OS) and ECU-Agriculture (ECU-A).[1] The Open Space designation as defined under Section 65560 of the Government Code, is any parcel or area of land or water which is essentially unimproved and devoted to an open-space use. The ECU-Agricultural designation is defined as irrigated lands which are suitable for the cultivation of crops and the raising of livestock within the boundaries of an Existing Community designated area and encompasses parcels of less than the prescribed minimum lot area.[2] Development of the project site with farmworker housing is allowable under the 2040 General Plan with the approval of a planned development permit.

1.4 Zoning

The project site is zoned with a mix of Open Space (OS-160 ac) and Agricultural Exclusive (AE-40 ac). According to the Non-Coastal Zoning Ordinance (NCZO) Section 8104-1.1, the OS zone permits the following land uses: dwellings (including single-family, two-family, multi-family, and accessory dwelling units), employee housing, farmworker housing complexes, transitional and supportive housing, and care facilities (such as day care centers and intermediate care facilities).[3] In addition, according to NCZO Section 8104-1.2, the purpose of the AE zone is to preserve and protect commercial agricultural lands as a limited and irreplaceable resource, to preserve and maintain agriculture as a major industry in Ventura County and to protect these areas from the encroachment of nonrelated uses which, by their nature, would have detrimental effects upon the agriculture industry.[4] The project site's existing zoning allows for the development of farmworker housing with approval of a planned development permit.

1.5 Surrounding Land Uses

Surrounding land uses include a mix of very low- and low-density residential areas, as well as industrial and commercial land uses. The project site is bordered by residential housing to the north, open space to the east, additional residential housing and a dog kennel to the south, and vacant industrial land to the west.

1.6 Description of Project

The proposed project involves construction of a 328-unit farmworker housing complex, restricted to farmworkers who qualify as lower income (100 percent affordable), which is classified as individuals and families whose income is 80 percent and below the area median income. The housing complex would be constructed on three parcels (Parcels 1, 2, and 3) totaling 19.8-acres. The project would set aside the remaining approximately 63-acre parcel (Parcel 4), as a conservation parcel that would be transferred to a Planning Director-approved conservation organization or public agency to remain as

[1] 'ECU' refers to Existing Communities and Urban designated areas

[4] ibid

open space in perpetuity. The existing farmhouse on the project site would be demolished while the existing orchard would be retained on Parcel 4. The proposed project land uses are illustrated in the Tentative Parcel Map, Figure 3.

The project would include construction of 328 residential units within 18 buildings, developed in three phases. Phase 1 would consist of 92 units within five residential buildings on 6.11-acres. Phase 2 would consist of 104 units within six residential buildings on 4.31-acres. Phase 3 would be developed with 132 units within seven buildings on 8.66 acres. Each residential building would consist of a mix of one-, two-, and three-bedroom units, and would vary between 12 and 24 units. The project phasing plan is depicted in Figure 4.

The development would also involve the construction of one free standing community center, a second community center within one of the residential buildings, two maintenance buildings, and eight trash enclosures. Residential amenities would be comprised of play fields, a teen/adult recreation amenity, playground equipment, a community garden, walking paths, and electric vehicle (EV) charging stations. The proposed project would feature a community center with an active area in the northwestern corner of the project site, a playground for children aged five to twelve in the southeastern corner, another playground for children aged two to five in the southeastern corner, and a central green recreation plaza located near the heart of the residential area. Covenants, conditions, and restrictions (CC&Rs) will be established to outline the maintenance and operation obligations for the access easements, community centers, and recreational facilities and mutual rights of access to the amenities between the three residential parcels.

The proposed residential structures would feature a combination of one-, two-, and three-story buildings, with a maximum height of 35 feet. The proposed buildings would be designed in a modern Spanish Colonial style with tile roofing, dark vinyl windows, beige cement plaster, dark brown gutters and downspouts, light brown beams, rafter tails and doors, and decorative tiles. Table 2 provides further project development details. Figure 5 depicts the conceptual project site plan and Figure 6 through Figure 10 provide visual renderings of the proposed building elevations.

Table 2 Project Summary

Project Component	Phase 1	Phase 2	Phase 3

Figure 9 Building Type D Elevations

Figure 10 Building Type E, Maintenance and Trash Elevations

Site Access and Parking

Regional access to the site is provided by the Ojai Freeway (SR-33). Local site access and internal circulation would be provided by two driveways off Ventura Avenue and private interior streets. A connection to Floral Drive in the northwest corner would be provided for emergency use only, with a locked emergency access gate only available to first responders. The project proposes 30-foot-wide access roads that would extend through the project site before ending at the eastern boundary of the site. The access roads would provide access to all proposed parking spaces and garages and would enable internal circulation of vehicles and bicycles on-site.

The proposed project would feature 565 parking spaces, including 27 ADA spaces and guest parking. Additionally, the project would provide EV charging stations in accordance with CALGreen requirements.

Utilities

The project would require new connections to existing utilities infrastructure, including water, wastewater, and electricity. The buildings would be all-electric, and no natural gas would be supplied to the project site. The project would be served by Ojai Valley Sanitation District for sewer, Ventura Water for water, and Southern California Edison for electricity.

Landscaping

The project would add 188,957 square feet of landscaping to the residential portion of the project site. Project landscaping would include trees, succulents, and shrubs throughout the project site. The project would involve the removal of six protected trees, including five heritage trees and one native protected tree. In addition to removal, there would be encroachment into the Tree Protection Zones (TPZ) of four other protected trees during construction. The project landscaping plan would provide for replacement trees or payment of an in-lieu fee consistent with NCZO Sec. 8107-25 requirements. Planting would be split into three zones (Zones 0, 1, and 2) throughout the project site following a planting plan that would comply with the Ventura County Fire Department (VCFD) fire clearance requirements per VCFD Standard 515.

Zone 0 would contain no trees and consist of non-woody, small herbaceous or succulent plants. These plants would be spaced at least twice their height apart. Additionally, designers and contractors would adhere to fire clearance requirements regarding setbacks, vine placement, and combustible materials. Zone 1 would include trees planted 20 feet apart, with no canopy extending within 10 feet of buildings. Shrubs would have a maximum height and width of four feet, spaced at twice their height. Groundcovers would be no taller than 12 inches, with groupings not exceeding 200 square feet and spaced at twice their height. Zone 2 would include trees planted 10 feet apart. Shrub groupings would not exceed four feet in height or 50 square feet in area. Individual shrubs would have a maximum height of six feet and width of four feet, spaced at twice their height. Ground covers would be no taller than 18 inches, with groupings not exceeding 500 square feet and spaced at twice their height. The plant palette would be comprised of non-invasive species known to thrive in the local mediterranean climate and soil condition.

Figure 11 Conceptual Landscape Plan

Project Construction

Project construction would be developed in three phases. Phase 1 construction would occur over approximately 20 months and would involve approximately 14 days of demolition, 90 days of site preparation, 30 days of grading, 14 months of building construction, and 30 days of architectural coating. Excavation and trenching for utilities would involve a maximum depth of up to approximately 10 feet below ground surface. Phase 1 would be operational in 2028.

Phase 2 construction would occur over approximately 20 months and would involve approximately 90 days of site preparation, 30 days of grading, 14 months of building construction, and 30 days of architectural coating. Excavation and trenching for utilities would involve a maximum depth of up to approximately 10 feet below ground surface. Phase 2 would be operational in 2030.

Phase 3 construction would occur over approximately 20 months and would involve approximately 90 days of site preparation, 30 days of grading, 14 months of building construction, and 30 days of architectural coating. Excavation and trenching for utilities would involve a maximum depth of up to approximately 10 feet below ground surface. Phase 3 would be operational in 2032.

A total of 5,700 sf of existing buildings and accessory structures would be demolished and removed from the site. A total of 17,000 cubic yards of soil would be imported during project construction. Exported soil, demolished building materials, and construction waste is anticipated to be taken to Toland Road Landfill located approximately 17.6 miles northeast of the project site.

2 Background

2.1 Overview of Sound Measurement

Sound is a vibratory disturbance created by a moving or vibrating source, which is capable of being detected by the hearing organs. Noise is defined as sound that is loud, unpleasant, unexpected, or undesired and may therefore be classified as a more specific group of sounds. The effects of noise on people can include general annoyance, interference with speech communication, sleep disturbance, and, in the extreme, hearing impairment (California Department of Transportation [Caltrans] 2013).

Noise levels are commonly measured in decibels (dB) using the A-weighted sound pressure level (dBA). The A-weighting scale is an adjustment to the actual sound pressure levels so that they are consistent with the human hearing response, which is most sensitive to frequencies around 4,000 Hertz and less sensitive to frequencies around and below 100 Hertz (Kinsler, et. al. 1999). Decibels are measured on a logarithmic scale that quantifies sound intensity in a manner similar to the Richter scale used to measure earthquake magnitudes. A doubling of the energy of a noise source, such as doubling of traffic volume, would increase the noise level by 3 dB; dividing the energy in half would result in a 3 dB decrease (Crocker 2007).

Human perception of noise has no simple correlation with sound energy. The perception of sound is not linear in terms of dBA or in terms of sound energy. Two sources do not "sound twice as loud" as one source. It is widely accepted that the average healthy ear can barely perceive changes of 3 dBA, increase or decrease (i.e., twice the sound energy); that a change of 5 dBA is readily perceptible; and that an increase (or decrease) of 10 dBA sounds twice (half) as loud (Crocker 2007).

Sound changes in both level and frequency spectrum as it travels from the source to the receptor. The most obvious change is the decrease in level as the distance from the source increases. The manner by which noise reduces with distance depends on factors such as the type of sources (e.g., point or line, the path the sound will travel, site conditions, and obstructions). Noise levels from a point source typically attenuate, or drop off, at a rate of 6 dBA per doubling of distance (e.g., construction, industrial machinery, ventilation units). Noise from a line source (e.g., roadway, pipeline, railroad) typically attenuates at about 3 dBA per doubling of distance (Caltrans 2013). The propagation of noise is also affected by the intervening ground, known as ground absorption. A hard site, such as a parking lot or smooth body of water, receives no additional ground attenuation and the changes in noise levels with distance (drop-off rate) result from simply the geometric spreading of the source. An additional ground attenuation value of 1.5 dBA per doubling of distance applies to a soft site (e.g., soft dirt, grass, or scattered bushes and trees) (Caltrans 2013). Noise levels may also be reduced by intervening structures; the amount of attenuation provided by this "shielding" depends on the size of the object and the frequencies of the noise levels. Natural terrain features such as hills and dense woods, and man-made features such as buildings and walls, can significantly alter noise levels. Generally, any large structure blocking the line of sight will provide at least a 5-dBA reduction in source noise levels at the receptor (Federal Highway Administration [FHWA] 2011). Structures can substantially reduce exposure to noise as well. The FHWA's guidelines indicate that modern building construction generally provides an exterior-to-interior noise level reduction of 20 to 35 dBA with closed windows.

The impact of noise is not a function of loudness alone. The time of day when noise occurs, and the duration of the noise are also important factors of project noise impact. Most noise that lasts for more

than a few seconds is variable in its intensity. Consequently, a variety of noise descriptors have been developed. One of the most frequently used noise metrics is the equivalent noise level (L_{eq}); it considers both duration and sound power level. L_{eq} is defined as the single steady A-weighted level equivalent to the same amount of energy as that contained in the actual fluctuating levels over time. Typically, L_{eq} is summed over a one-hour period. L_{max} is the highest root mean squared (RMS) sound pressure level within the sampling period, and L_{min} is the lowest RMS sound pressure level within the measuring period (Crocker 2007).

Noise that occurs at night tends to be more disturbing than that occurring during the day. Community noise is usually measured using Day-Night Average Level (DNL), which is the 24-hour average noise level with a +10 dBA penalty for noise occurring during nighttime (10:00 p.m. to 7:00 a.m.) hours; it is also measured using Community Noise Equivalent Level (CNEL), which is the 24-hour average noise level with a +5 dBA penalty for noise occurring from 7:00 p.m. to 10:00 p.m. and a +10 dBA penalty for noise occurring from 10:00 p.m. to 7:00 a.m. (Caltrans 2013). Noise levels described by DNL and CNEL usually differ by about 1 dBA. The relationship between the peak-hour L_{eq} value and the DNL/CNEL depends on the distribution of traffic during the day, evening, and night. Quiet suburban areas typically have CNEL noise levels in the range of 40 to 50 dBA, while areas near arterial streets are in the 50 to 60-plus CNEL range. Normal conversational levels are in the 60 to 65-dBA L_{eq} range; ambient noise levels greater than 65 dBA L_{eq} can interrupt conversations (Federal Transit Administration [FTA] 2018).

2.2 Vibration

Groundborne vibration of concern in environmental analysis consists of the oscillatory waves that move from a source through the ground to adjacent structures. The number of cycles per second of oscillation makes up the vibration frequency, described in terms of Hz. The frequency of a vibrating object describes how rapidly it oscillates. The normal frequency range of most groundborne vibration that can be felt by the human body starts from a low frequency of less than 1 Hz and goes to a high of about 200 Hz (Crocker 2007).

While people have varying sensitivities to vibrations at different frequencies, in general they are most sensitive to low-frequency vibration. Vibration in buildings, such as from nearby construction activities, may cause windows, items on shelves, and pictures on walls to rattle. Vibration of building components can also take the form of an audible low-frequency rumbling noise, referred to as groundborne noise. Groundborne noise is usually only a problem when the originating vibration spectrum is dominated by frequencies in the upper end of the range (60 to 200 Hz), or when foundations or utilities, such as sewer and water pipes, physically connect the structure and the vibration source (FTA 2018). Although groundborne vibration is sometimes noticeable in outdoor environments, it is almost never annoying to people who are outdoors. The primary concern from vibration is that it can be intrusive and annoying to building occupants and vibration-sensitive land uses.

Vibration energy spreads out as it travels through the ground, causing the vibration level to diminish with distance away from the source. High-frequency vibrations diminish much more rapidly than low frequencies, so low frequencies tend to dominate the spectrum at large distances from the source. Discontinuities in the soil strata can also cause diffractions or channeling effects that affect the propagation of vibration over long distances (Caltrans 2020). When a building is impacted by vibration, a ground-to-foundation coupling loss will usually reduce the overall vibration level.

However, under rare circumstances, the ground-to-foundation coupling may actually amplify the vibration level due to structural resonances of the floors and walls.

Vibration amplitudes are usually expressed in peak particle velocity (PPV) in inches per second (in./sec.). PPV is defined as the maximum instantaneous positive or negative peak of a vibration signal. PPV is often used in monitoring of blasting and construction vibration because it is related to the stresses that are experienced by buildings (Caltrans 2020).

2.3 Sensitive Receivers

Noise exposure goals for various types of land uses reflect the varying noise sensitivities associated with those uses. The Hazard and Safety Element of the of the Ventura County 2040 General Plan states that noise sensitive land uses are generally considered to include those uses where noise exposure could result in health-related risks to individuals, as well as places where quiet is an essential element of their intended purpose noise sensitive land uses as (Ventura County 2020). Noise sensitive receivers are determined to be: residences; schools; historic sites; cemeteries; parks, recreation, and open space areas; hospitals and care facilities; sensitive wildlife habitats, including the habitat of rare, threatened, or endangered species; hotels and other short-term lodging (e.g., bed and breakfasts, and motels); places of worship; and libraries. Noise sensitive receptors near the project site include single-family residences adjacent to the northern and southern project boundary. The nearest school is the La Petite Academy of Ventura, located approximately 2.1 miles to the south.

Vibration sensitive receivers are similar to noise sensitive receivers, such as residences, and institutional uses, such as schools, churches, and hospitals. However, vibration sensitive receivers also include buildings where vibrations may interfere with vibration-sensitive equipment. Vibration sensitive receivers nearest to the site include single-family residences adjacent to the northern and southern project boundary.

2.4 Project Noise Setting

The most prominent source of noise in the project site vicinity is vehicular traffic from the SR-33 freeway and other surrounding roadways. To characterize ambient sound levels at and near the project site, four 15-minute sound level measurements were conducted on March 18, 2025, and one 24-hour measurement was conducted on March 18-19, 2025. Short-term (ST) noise Measurement 1 was taken near the midpoint of the western boundary of project site; ST-2 was taken near the southeast corner of on-site farm orchard; ST-3 was taken at the southern end of Floral Drive and ST-4 was taken near southeast corner of Norway Drive and East Bounds Drive. The 24-hour measurement (LT1) was placed near the midpoint of the western boundary of project site. Noise measurement locations are shown in Figure 12.

The measurements were completed using a Piccolo II sound level meter fitted with a windscreen. The meter complies with American National Standards Institute (ANSI) Standard S1.4. The sound level meters were set to “slow” response and “A” weighting (dBA). The meters were calibrated prior to and after the monitoring period. All measurements were at least five feet above the ground and away from reflective surfaces. Table 3 and Table 4 summarize the results of the noise measurements. Detailed sound level measurement data are included in Appendix A.

Table 3 Project Site Noise Monitoring Results – Short Term

Measurement	Location	Sample Times	Approximate Distance to Primary Noise Source	L_{eq} (dBA)	L_{max} (dBA)	L_{min} (dBA)
ST-1	Near the midpoint of the western boundary of project site	3:14–3:29 p.m.	Approximately 40 feet to centerline of North Ventura Ave. Approximately 230 feet to the nearest lane of SR-33.	67	85	51
ST-2	Near the southeast corner of on-site farm orchard.	3:14–3:29 p.m.	Approximately 1,545 feet to centerline of North Ventura Avenue. Approximately 1,690 feet to the nearest lane of SR-33.	48	55	42
ST-3	Southern end of Floral Drive	3:14–3:29 p.m.	Approximately 130 feet to centerline of East Bounds Road.	56	70	43
ST-4	Near southeast corner of Norway Drive and E. Bounds Drive	3:35–3:50 p.m.	Approximately 60 feet east of Norway Drive. Approximately 275 feet east of SR-33.	52	67	44

Approximate noise measurement locations are shown in Figure 12.

Table 4 Project Site Noise Monitoring Results – Long Term

Sample Time	dBA L_{eq}	Sample Time	dBA L_{eq}
LT1 – Midpoint of Western Boundary of Project Site, March 18–19, 2025			
2:00 p.m.	63.9	2:00 a.m.	51.3
3:00 p.m.	67.1	3:00 a.m.	51.8

2.5 Regulatory Setting

Federal

FTA Transit and Noise Vibration Impact Assessment Manual

The Federal Transit Authority (FTA) provides reasonable criteria for assessing construction vibration impacts based on the potential for adverse community reaction in their *Transit and Noise Vibration Impact Assessment Manual* (FTA 2018).

State

The state of California regulates freeway noise, sets standards for sound transmission, provides occupational noise control criteria, identifies noise standards, and provides guidance for local land use compatibility. State law requires each county and city to adopt a General Plan that includes a Noise Element prepared per guidelines adopted by the Governor's Office of Planning and Research. The purpose of the Noise Element is to limit the exposure of the community to excessive noise levels. The California Environmental Quality Act requires all known environmental effects of a project be analyzed, including environmental noise impacts.

California Building Code (CCR Title 24, Part 2)

California adopted noise insulation standards for residential buildings (Title 24, Part 2, California Code of Regulations, section 1206, et. seq.). Title 24 establishes standards for interior room noise (attributable to outside noise sources). A project must be designed to limit intruding noise to an interior CNEL (or L_{dn}) of at least 45 dBA in any habitable room.

Local

Ventura County 2040 General Plan

The Hazards and Safety Element of the 2040 General Plan identifies sources of noise and provides goals, objectives, and policies to ensure that noise from various sources, including transportation and stationary sources, does not create an unacceptable noise environment. The following policies and implementation actions from the Noise section of the Hazards and Safety Element are relevant to the proposed project (Ventura County 2020):

POLICIES

- **Policy HAZ-9.1: Limiting Unwanted Noise.** Ventura County shall prohibit discretionary development which would be impacted by noise or generate project-related noise which cannot be reduced to meet the standards prescribed in Policy Haz-9.2. This policy does not apply to noise generated during the construction phase of a project.
- **Policy HAZ-9.2: Noise Compatibility Standards.** Ventura County shall review discretionary development for noise compatibility with surrounding uses. Ventura County shall determine noise based on the following standards:

    1) New noise sensitive uses proposed to be located near highways, truck routes, heavy industrial activities and other relatively continuous noise sources shall incorporate noise control measures so that indoor noise levels in habitable rooms do not exceed Community Noise Equivalent Level (CNEL) 45 and outdoor noise levels do not exceed CNEL 60 or Leq1H of 65 dB(A) during any hour.

2) New noise sensitive uses proposed to be located near highways, truck routes, heavy industrial activities and other relatively continuous noise sources shall incorporate noise control measures so that indoor noise levels in habitable rooms do not exceed Community Noise Equivalent Level (CNEL) 45 and outdoor noise levels do not exceed CNEL 60 or Leq1H of 65 dB(A) during any hour.
3) New noise sensitive uses proposed to be located near airports:

   a) Shall be prohibited if they are in a Community Noise Equivalent Level (CNEL) 65 dB or greater noise contour; or

   b) Shall be permitted in the Community Noise Equivalent Level (CNEL) 60 dB to CNEL 65 dB noise contour area only if means will be taken to ensure interior noise levels of CNEL 45 dB or less.

4) New noise generators, proposed to be located near any noise sensitive use, shall incorporate noise control measures so that ongoing outdoor noise levels received by the noise sensitive receptor, measured at the exterior wall of the building, does not exceed any of the following standards:

   a) Leq1H of 55dB(A) or ambient noise level plus 3dB(A), whichever is greater, during any hour from 6:00 a.m. to 7:00 p.m.; control measures so that indoor noise levels in habitable rooms do not exceed

   b) Leq1H of 50dB(A) or ambient noise level plus 3dB(A), whichever is greater, during any hour from 7:00 p.m. to 10:00 p.m.; and
   c) Leq1H of 45dB(A) or ambient noise level plus 3dB(A), whichever is greater, during any hour from 10:00 p.m. to 6:00 a.m.

5) Construction noise shall be evaluated and, if necessary, mitigated in accordance with the Construction Noise Threshold Criteria and Control Measures (CNTCCP 2010).

- **Policy HAZ-9.4: Acoustical Analysis Required.** Ventura County shall require an acoustical analysis by a qualified acoustical engineer for discretionary development involving noise exposure or noise generation in excess of the established standards. The analysis shall provide documentation of existing and projected noise levels at on-site and off-site receptors and shall recommend noise control measures for mitigating adverse impacts.
- **Policy HAZ-9.7: Noise Control Priorities.** The priorities for noise control for discretionary development shall be as follows:

  1) Reduction of noise emissions at the source.

  2) Attenuation of sound transmission along its path, using barriers, landform modification, dense plantings, building orientation and placement, and the like.

  3) Rejection of noise at the reception point using noise control building construction, hearing protection or other means.

- **Policy HAZ-9.8: Implement Noise Control Measures for Traffic Noise.** Ventura County shall require noise control measures to be implemented along roadways for new discretionary development generating traffic noise if the following circumstances would exist:

  1) The discretionary development would result in an increase in traffic noise levels of 3 dBA or greater in an area where traffic noise levels under existing conditions exceed a County noise compatibility standard stated in Policy HAZ 9.2

Ventura County Construction Noise Threshold Criteria and Control Plan

According to the Ventura County Construction Noise Threshold Criteria and Control Plan, construction work should comply with Ventura County of Ventura's daytime construction noise threshold criteria (NTC). Normally, no evening or nighttime construction activity is permitted in areas having noise sensitive receptors. However, in the event such activity is permitted, reduced noise threshold criteria are provided for construction that might occur during evening and /or nighttime hours. Emergency work is exempt from these construction noise thresholds. The thresholds are described below.

Daytime Construction. Daytime (7:00 a.m. to 7:00 p.m. Monday through Friday and from 9:00 a.m. to 7:00 p.m. Saturday, Sunday and local holidays) generally means any time period not specifically defined as a more noise sensitive time period. The daytime construction noise threshold criteria are given in Table 5. Depending on project duration, the daytime noise threshold criteria shall be the greater of the fixed Leq(h) limit (which includes non-construction evening and nighttime noise) or the measured ambient Leq(h) plus 3 dB. The only sensitive daytime receivers that these thresholds apply to are hospitals, nursing homes, schools, churches, and libraries. County construction noise thresholds only apply to residential receivers during the evening (7:00 p.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 p.m.).

Table 5 Daytime Construction Activity Noise Threshold Criteria

Construction Duration Affecting Noise-sensitive Receptors	Noise Threshold Criteria shall be the greater of these noise levels at the nearest receptor area or 10 feet from the nearest noise-sensitive building	
	Fixed Leq(h), dBA	Hourly Equivalent Noise Level (Leq), dBA[1, 2]
0 to 3 days	75	Ambient Leq(h) + 3 dB
4 to 7 days	70	Ambient Leq(h) + 3 dB
1 to 2 weeks	65	Ambient Leq(h) + 3 dB
2 to 8 weeks	60	Ambient Leq(h) + 3 dB
Longer than 8 weeks	55	Ambient Leq(h) + 3 dB

[1] The instantaneous Lmax shall not exceed the NTC by 20 dBA more than 8 times per daytime hour.

[2] Local ambient Leq measurements shall be made on any mid-weekday prior to project work.

Note: The only sensitive daytime receivers that these thresholds apply to are hospitals, nursing homes, schools, churches, and libraries. County noise thresholds only apply to residential receivers during the evening (7:00 p.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 p.m.), in which project construction would not occur.

Source: County of Ventura 2010

Maximum Construction Noise. In addition, the construction-related, slow response, instantaneous maximum noise (Lmax) shall not exceed the noise threshold criteria by 20 dBA more than eight times per daytime hour, more than six times per evening hour and more than four times per nighttime hour.

3 Methodology

3.1 Construction Noise

Construction noise was estimated using the Federal Highway Administration (FHWA) Roadway Construction Noise Model (RCNM) (FHWA 2006). RCNM predicts construction noise levels for a variety of construction operations based on empirical data and the application of acoustical propagation formulas. Using RCNM, construction noise levels were estimated at noise sensitive receivers near the project site. RCNM provides reference noise levels for standard construction equipment, with an attenuation of 6 dBA per doubling of distance for stationary equipment.

Variation in power imposes additional complexity in characterizing the noise source level from construction equipment. Power variation is accounted for by describing the noise at a reference distance from the equipment operating at full power and adjusting it based on the duty cycle of the activity to determine the L_{eq} of the operation (FHWA 2018). Each phase of construction has a specific equipment mix, depending on the work to be accomplished during that phase. Each phase also has its own noise characteristics; some will have higher continuous noise levels than others, and some have high-impact noise levels.

Construction activity would result in temporary noise in the project area, exposing surrounding sensitive receivers to increased noise levels. The project would involve demolition, site preparation, grading, building construction, paving, and architectural coating. Construction noise would typically be higher during the heavier periods of initial construction (i.e., demolition, grading and site preparation) and would be lower during the later construction phases. Typical heavy construction equipment during project grading could include excavators, scrapers, loaders, and rollers. It is assumed that diesel engines would power all construction equipment. Construction equipment would not all operate at the same time or location. In addition, construction equipment would not be in constant use during the 8-hour operating day.

Construction equipment is typically dispersed in various areas of a site, with only a limited amount of equipment operating near a given location at a particular time. For this reason, the FTA's *Transit Noise and Vibration Impact Assessment* (FTA 2018) document (page 177) recommends to "assume that all equipment operates at the center of the project." Therefore, it is standard industry practice to analyze average construction noise from the center of the project site, which represents the approximate center of where noise would be generated because equipment moves around the project site throughout the workday.

The project would not include evening or nighttime construction activity; therefore, the applicable construction noise threshold is the Ventura County daytime construction noise threshold. As described in Section 2.5, *Regulatory Setting*, the Ventura County daytime construction noise threshold applies to hospitals, nursing homes, schools, churches, and libraries. County construction noise thresholds only apply to residential receivers during the evening (7:00 p.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 p.m.) (County of Ventura 2010). Therefore, the closest sensitive receptor under the Ventura County daytime construction noise standard is La Petite Academy to the south. Each of the three phases of construction would have construction at the southern boundary of the project site, and therefore construction from each phase would be located at the same distance to La Petite Academy of 2.1 miles (RCNM calculations are included in Appendix B).

3.2 Groundborne Vibration

Operation of the proposed project would not include any substantial vibration sources. Therefore, construction activities have the greatest potential to generate ground-borne vibration affecting nearby receptors, especially during paving of the at-grade parking of the project site. The greatest vibratory source during construction would be a vibratory roller. Neither blasting nor pile driving would be required for construction of the proposed project. Construction vibration estimates are based on vibration levels reported by the FTA. Table 6 shows typical vibration levels for various pieces of construction equipment used in the assessment of construction vibration (FTA 2018).

Table 6 Vibration Source Levels for Construction Equipment

	Approximate Vibration Level (in/sec PPV)		
Equipment	**25 feet**	**50 feet**	**100 feet**
Small Bulldozer	0.003	0.001	0.0007
Jackhammer	0.035	0.016	0.008
Loaded Truck	0.076	0.036	0.017
Large Bulldozer	0.089	0.042	0.019
Vibratory Roller	0.210	0.098	0.046

Source: FTA 2018

Vibration limits used in this analysis to determine a potential impact to local land uses from construction activities are based on information contained in the FTA's *Transit Noise and Vibration Impact Assessment*. Maximum recommended vibration limits by the FTA are identified in Table 7.

Table 7 Criteria for Vibration Damage Potential

Building Category	PPV (in/sec)
I. Reinforced concrete, steel, or timber (no plaster)	0.5
II. Engineered concrete and masonry (no plaster)	0.3
III. Nonengineered timber and masonry buildings	0.2
IV. Buildings extremely susceptible to vibration damage	0.12

in/sec = inches per second; PPV = peak particle velocity

Source: FTA 2018

Based on FTA recommendations, limiting vibration levels to below 0.2 in/sec PPV at residential structures would prevent architectural damage. These limits are applicable regardless of the frequency of the source.

3.3 Operational Noise Sources

Noise sources associated with operation of the proposed project would consist of low speed on-site vehicular noise, landscaping maintenance, general conversations, and mechanical equipment (e.g., heating, ventilation, and air conditioning [HVAC] units).

Mechanical Equipment

The primary mechanical equipment noise generator from the project would be HVAC units. Based on review of various manufacturer specifications for residential applications, a representative noise level of 63 dBA L_{eq} at 3 feet for a 2-ton Carrier 24ANB7-3PD was selected (see Appendix C for manufacturer's specifications). According to information provided by the project developer, HVAC units were assumed to be located on the rooftops of each building, and distances were based on the site plan provided by RRM Design Group, dated March 22, 2024 (RRM 2024). For a conservative scenario, the HVAC units were assumed to operate continuously for 24 hours.

Transportation Noise

Based on information provided by the proposed project's traffic study, prepared by TJW Engineering, Inc (TJW 2024), the project would generate up to 1,210 daily trips on Canada Larga Road, and up to 1,246 on North Ventura Avenue that would increase noise levels on nearby roadways. The proposed project would not make alterations to roadway alignments or substantially change the vehicle classifications mix on local roadways. Therefore, the primary factor affecting off-site noise levels would be increased traffic volumes.

On-site Noise and Land Use Compatibility

The project's consistency with exterior and interior noise land use compatibility standards of Ventura County was determined using the long-term noise measurements completed at the project site (shown above in Table 4).

4 Significance Thresholds

To determine whether a project would have a significant noise impact, Appendix G of the *CEQA Guidelines* requires consideration of whether a project would result in:

1. Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.
2. Generation of excessive groundborne vibration or groundborne noise levels.
3. For a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, exposure of people residing or working in the project area to excessive noise levels.

4.1 Construction Noise

Ventura County 2040 General Plan Policy HAZ-9.2 provides criteria for assessing construction noise impacts based on the potential for adverse community reaction in their Ventura County Construction Noise Threshold Criteria and Control Plan (Ventura County 2010). For projects lasting longer than 8 weeks, the daytime noise threshold is 55 dBA L_{eq} or ambient $L_{eq(hour)}$ + 3 dB, whichever is greater. The Construction Noise Threshold Criteria and Control Plan states that the only sensitive daytime receivers that these thresholds apply to include hospitals, nursing homes, schools, churches, and libraries. County noise thresholds only apply to residential receivers during the evening (7:00 p.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 p.m.), in which project construction would not occur.

4.2 Groundborne Vibration

Vibration limits used in this analysis to determine a potential impact to local land uses from on-site truck activities are based on information contained in the FTA *Transit Noise and Vibration Impact Assessment Manual* (FTA 2018). Groundborne vibration levels that could induce potential architectural damage to buildings are identified in Table 8. Based on FTA recommendations, limiting vibration levels to below 0.2 in/sec PPV at non-engineered timber and masonry buildings (which would apply to any nearby residential structures) would prevent architectural damage.

Table 8 Groundborne Vibration Architectural Damage Criteria

Building Category	PPV (in/sec)
I. Reinforced concrete, steel, or timber (no plaster)	0.5
II. Engineered concrete and masonry (no plaster)	0.3
III. Nonengineered timber and masonry buildings	0.2
IV. Buildings extremely susceptible to vibration damage	0.12

in/sec = inches per second; PPV = peak particle velocity

Source: FTA 2018

4.3 On-Site Stationary Operational Noise

Ventura County has adopted exterior noise standards in the 2040 General Plan Policy HAZ-9.2 regulating all mechanical equipment buildings, including heating, ventilation, and HVAC. The project would result in a significant impact if noise from project stationary operational noise sources exceeds 45 dBA within ten feet of a building exterior of any noise sensitive receptor.

4.4 Traffic Noise

Noise levels affecting the project site would be primarily influenced by traffic noise from SR-33, North Ventura Avenue and surrounding roadways adjacent to the project site. Policy HAZ-9.8 states that Ventura County shall require noise control measures to be implemented along roadways for new discretionary development generating traffic noise if the following circumstances would exist:

- The discretionary development would result in an increase in traffic noise levels of 3 dBA or greater in an area where traffic noise levels under existing conditions exceed a County noise compatibility standard stated in Policy HAZ 9.2.

4.5 Impact of the Environment on the Project

As a result of the Supreme Court decision regarding the assessment of the environment's impacts on projects (*California Building Industry Association [CBIA] v. Bay Area Air Quality Management District [BAAQMD]*, 62 Cal. 4th 369 [No. S 213478] issued December 17, 2015), it is generally not considered the purview of the CEQA process to evaluate the impact of existing environmental conditions on a proposed project. Therefore, this environmental analysis does not consider the potential impacts of the environment (i.e., existing noise) on the project.

5 Impact Analysis

5.1 Issue 1 – Temporary and Permanent Noise Increase

Construction

Phase 1 Construction

Project construction activities for Phase 1 are anticipated to occur over the course of 20 months, beginning in 2026. The Ventura County Construction Noise Threshold and Control Plan defines noise-sensitive receivers according to their typical sensitive time period. Residential uses are considered sensitive during the evening and nighttime hours (7:00 p.m. to 7:00 a.m.), while schools, churches, and libraries are considered sensitive during the daytime hours when in use (7:00 a.m. to 7:00 p.m.) (Ventura County 2010). Project construction would only occur during the daytime hours; therefore, noise-sensitive residences would not be exposed to nighttime construction noise. As described in Section 3.1, *Construction Noise*, the nearest sensitive receptor during project construction would be La Petit Academy, located to the south of the project site.

To determine construction noise impacts, noise was estimated using the FHWA RCNM Version 1.1, shown in Table 9. Construction equipment is typically dispersed in various areas of a site, with only a limited amount of equipment operating near a given location at a particular time. For this reason, the FTA 2018 *Transit Noise and Vibration Impact Assessment* document (page 177) recommends to "assume that all equipment operates at the center of the project." Therefore, it is standard industry practice to analyze average construction noise from the center of the project site, which represents the approximate center of where noise would be generated because equipment moves around the project site throughout the workday. Over the course of a typical construction day during Phase 1, construction equipment would be located approximately 2.1 miles (10,910 feet) from the center of construction activity to the La Petite Academy of Ventura property line to the south. Table 9 shows the construction noise levels attributable to each construction phase modeled from the center of Phase 1 of construction.

Table 9 Estimated Noise Levels by Construction Phase at Sensitive Receptors – Phase 1

	L_{eq} dBA	
Construction Activity Phase	**RCNM Reference Noise Level (50 feet)**	**La Petite Academy of Ventura to the South (2.1 miles)**
Demolition	85	38
Site Preparation	83	36
Grading	83	36
Building Construction	79	32
Paving	78	31
Architectural Coating	74	27

Notes: Calculations performed with the FHWA's RCNM software are included in Appendix B.

Noise levels rounded to the nearest whole number.

As shown in Table 9, construction noise levels of up to 38 dBA L_{eq} during demolition would not exceed the Ventura County daytime construction noise standard of 55 dBA L_{eq}. Therefore, Phase 1 construction noise impacts would be less than significant.

Phase 2 Construction

Project construction activities for Phase 2 are anticipated to occur over the course of 20 months and begin in 2028. To determine construction noise impacts under Phase 2, noise was estimated using the FHWA RCNM Version 1.1, shown in Table 10. Over the course of a typical construction day during Phase 2, construction equipment would be located approximately 2.1 miles (10,910 feet) from the center of construction activity to the La Petite Academy of Ventura property line to the south. Table 10 shows the construction noise levels attributable to each construction phase modeled during Phase 2 construction activity.

Table 10 Estimated Noise Levels by Construction Phase at Sensitive Receptors – Phase 2

	L_{eq} dBA	
Construction Activity Phase	**RCNM Reference Noise Level (50 feet)**	**La Petite Academy of Ventura to the South (2.1 miles)**
Site Preparation	83	36
Grading	83	36
Building Construction	79	32
Paving	78	31
Architectural Coating	74	27

Notes: Calculations performed with the FHWA's RCNM software are included in Appendix B.

Noise levels rounded to the nearest whole number.

As shown in Table 10, La Petite Academy would be exposed to noise levels of up to 36 dBA L_{eq} during Phase 2 site preparation and grading. The noise levels during Phase 2 construction would not exceed Ventura County's daytime construction noise standard of 55 dBA L_{eq}. Therefore, Phase 2 construction noise impacts would be less than significant.

Phase 3 Construction

Project construction activities for Phase 3 are anticipated to occur over the course of 20 months and begin in 2028. To determine construction noise impacts under Phase 3, noise was estimated using the FHWA RCNM Version 1.1, shown in Table 11Table 10. Over the course of a typical construction day during Phase 3, construction equipment would be located approximately 2.1 miles (10,910 feet) from the center of construction activity to the La Petite Academy of Ventura property line to the south. Table 11 shows the construction noise levels attributable to each construction phase modeled during Phase3 construction activity.

Table 11 Estimated Noise Levels by Construction Phase at Sensitive Receptors – Phase 3

Construction Activity Phase	L_{eq} dBA	
	RCNM Reference Noise Level (50 feet)	La Petite Academy of Ventura to the South (2.1 miles)
Site Preparation	83	36
Grading	83	36
Building Construction	79	32
Paving	78	31
Architectural Coating	74	27

Notes: Calculations performed with the FHWA's RCNM software are included in Appendix B.
Noise levels rounded to the nearest whole number.

As shown in Table 10, La Petite Academy would be exposed to noise levels of up to 36 dBA L_{eq} during Phase 3 site preparation and grading. The noise levels during Phase 3 construction would not exceed Ventura County's daytime construction noise standard of 55 dBA L_{eq}. Therefore, Phase 3 construction noise impacts would be less than significant.

Operation

Mechanical Equipment

The primary on-site operational noise source from the proposed project would be from mechanical equipment such as the HVAC units. To provide a reasonable worst-case analysis, three HVAC units operating simultaneously were modeled at the same location on the proposed roof closest to the nearest off-site sensitive receptor in order to calculate noise levels at the residential property line to the north. The three nearest HVAC units would be approximately 155 feet from the nearest off-site sensitive residential property line to the north. This is a conservative analysis as it does not account for shielding from buildings or roof setbacks from the project site to the surrounding uses.

Based upon a sound power level of 71 dBA, it is estimated that the sound power level of a single HVAC unit would generate an equivalent sound pressure level of 63 dBA at three feet. Based on the distance to the single-family residential property to the north, noise levels generated by the three HVAC units operating simultaneously would be approximately 34 dBA L_{eq} at 155 feet. HVAC noise would not exceed the nighttime threshold of 45 dBA $L_{eq(1\text{-}hour)}$ within ten feet of the building exterior of any noise sensitive receptor. All other sensitive receptors would be located further from the nearest HVAC units and would therefore be exposed to lower HVAC noise levels. Noise impacts associated with HVAC use would be less than significant.

Future Residents

In addition to mechanical equipment, the proposed project would generate noise from people gathering at the project site. The main noise source associated with future residents would be speech from conversations. Typically, a conversation between two people using a normal voice (not raised) at a distance of three feet is 60 dBA (Engineering ToolBox 2005). No amplified sound is proposed at any gathering location, and speech from conversations would quickly dissipate and would not interfere with surrounding outdoor activities and noise-sensitive uses. Furthermore, per Assembly Bill 1307 (2023), the effect of noise generated by residential project occupants and their guests is not a

significant effect on the environment. Impacts associated with gatherings would be less than significant.

Off-site Traffic Noise

The proposed project would generate new vehicle trips that would increase noise levels on nearby roadways, particularly on North Ventura Avenue and Canada Larga Road. Based on the traffic impact assessment prepared by TJW Engineering, Inc (TJW 2025), the proposed project would generate 1,578 daily trips, which would be distributed on the nearby roadways. Table 12 shows the existing trips compared to existing plus project trips, and the subsequent noise increase from the traffic.

Table 12 Project Traffic Noise Increases

Street	Segment	Existing ADT	Existing + Project ADT	Traffic Noise Increase (dBA CNEL)
Canada Larga Road	Between Ventura and Weldon Canyon	1,428	2,638	2.7
North Ventura Avenue	Between Canada Larga and Crooked Palm	3,112	4,358	1.5
North Ventura Avenue	Between Norway Drive and Los Cabos Lane	2,085	3,310	2.0

As shown in Table 12, the largest noise increase would occur on Canada Larga Road. The addition of 1,210 daily vehicle trips would result in a traffic noise increase of approximately 2.7 dBA CNEL. Traffic noise increases would be lower on the two segments of North Ventura Avenue. For traffic-related noise, impacts would be considered significant if project-generated traffic would result in exposure of sensitive receptors to an unacceptable increase in noise levels, which is a 3 dBA CNEL increase. The proposed project would not result in traffic noise increases greater than the traffic noise threshold of 3 dBA CNEL; therefore, impacts from off-site traffic would be less than significant.

5.2 Issue 2 – Vibration

Construction activities known to generate excessive ground-borne vibration, such as pile driving, would not be conducted by the proposed project. The greatest anticipated source of vibration during general project construction activities would be from a vibratory roller, which would be used approximately 60 feet from the nearest off-site residential building to the north. A vibratory roller would create approximately 0.210 in/sec PPV at 25 feet (FTA 2018). The estimated vibration level created by a vibratory roller at 60 feet is 0.056 in/sec PPV. Therefore, vibration from construction activity would be lower than the nonengineered timber and masonry buildings threshold of 0.2 in/sec PPV for the residential building to the north, and impacts would be less than significant.

Operation of the project would not include any substantial vibration sources and would be less than significant.

5.3 Issue 3 – Airport Noise

The Oxnard Airport is located 10 miles to the south of the project site. According to the most recent Airport Comprehensive Land Use Plan Update for Ventura County, the project site is located outside the airport noise contours for Oxnard Airport (Ventura County Airport Land Use Commission 2000).

There are no private airstrips near the project site. Therefore, the project would not expose people residing or working in the plan area to excessive airport noise levels. No impact would occur.

5.4 Issue 4 – On-Site Noise and Land Use Compatibility

Although not a CEQA issue, land use compatibility was studied to determine whether new residents of the project would be exposed to outdoor or indoor noise levels that exceed Ventura County's thresholds for informational purposes. The nearest exterior use area of the project site would be the community garden, which would be located approximately 530 feet from the centerline of SR-33. A long-term measurement was conducted on the western boundary of the site approximately 290 feet from the centerline of SR-33, as shown in Table 4. The measured 24-hour noise level was recorded as 68.6 CNEL. This measured noise level can be scaled for a line source to account for the distance to the centerline of SR-33 for the measurement to the distance of the exterior uses. Assuming a 10 dBA reduction in noise as a result of shielding from the on-site buildings, at a distance of 530 feet from the centerline, the assumed ambient noise level would be 56.0 dBA CNEL at the on-site community garden. Using the same methodology, at a distance of 680 feet from the centerline of SR-33, the assumed ambient noise level would be 54.9 dBA CNEL at the nearest on-site playground, and at a distance of 900 feet from the centerline of SR-33, the assumed ambient noise level would be 53.7 dBA CNEL at the basketball court. These values would be below the 60 CNEL standard for exterior uses; therefore, the project would be consistent with the exterior noise land use compatibility standards of Ventura County.

Typical modern building materials would be anticipated to attenuate noise levels from the exterior to interior by approximately 25 dBA L_{eq} (FHWA 2011). Therefore, with attenuation, interior noise levels would be approximately 43.6 dBA L_{eq}. This would be below Ventura County's 45 dBA L_{eq} standard for interior noise levels at a residential use.

6 Conclusions

Construction would generate noise levels of up to 38 dBA $L_{eq(hour)}$, which would not exceed Ventura County's construction noise thresholds at the nearby preschool of 55 dBA $L_{eq(hour)}$. Impacts would be less than significant.

The proposed project would introduce sources of operational noise to the site, including mechanical equipment, such as HVAC units. Operational noise levels would reach up to 34 dBA L_{eq}, which would be well below Ventura County General Plan nighttime standard of 45 dBA L_{eq}. Additionally, operational noise levels from the project would not exceed 45 dBA L_{eq} during nighttime hours at any point on the adjacent residential properties. Therefore, project operational stationary noise would be less than significant.

Vehicle trips associated with the proposed project would not increase noise levels by more than 3 dBA CNEL. Therefore, impacts associated with off-site noise sources would be less than significant.

Operation of the project would not include any substantial vibration sources. Groundborne vibration from construction activities, such as the use of a roller, would not exceed the applicable vibration thresholds. Therefore, vibration impacts would be less than significant.

The proposed project is not located within the noise contours for Oxnard Airport. Therefore, no substantial noise exposure would occur to construction workers or users of the project site from aircraft noise, and no impacts would occur.

Although not a CEQA issue, land use compatibility was studied to determine whether new residents of the project would be exposed to outdoor or indoor noise levels that exceed Ventura County's thresholds. Noise levels at outdoor community areas, such as the community garden, playground, and basketball courts, would not exceed Ventura County's threshold. Likewise, noise levels within the residences would not exceed Ventura County's threshold for interior noise.

24ANB7
Infinity™ 17 2–Stage Air Conditioner with Puron® Refrigerant 2 to 5 Nominal Tons

Carrier
turn to the experts

Product Data

INFINITY® SERIES

Carrier's Air Conditioners with Puron® refrigerant provide a collection of features unmatched by any other family of equipment. The 24ANB7 has been designed utilizing Carrier's Puron refrigerant. The environmentally sound refrigerant allows you to make a responsible decision in the protection of the earth's ozone layer.

This product has been designed and manufactured to meet Energy Star® criteria for energy efficiency when matched with appropriate coil components. Refer to the combination ratings in the Product Data for system combinations that meet Energy Star® guidelines.

NOTE: Ratings contained in this document are subject to change at any time. Always refer to the AHRI directory (www.ahridirectory.org) for the most up-to-date ratings information.

INDUSTRY LEADING FEATURES / BENEFITS

Efficiency

- 14 - 18 SEER / 11.5 - 13.7 EER
- Microtube Technology™ refrigeration system
- Indoor air quality accessories available

Sound

- Sound level as low as 69 dBA
- Quiet mount split post compressor grommets
- Forward-swept condenser fan blade
- Compressor sound hood
- Laminated steel compressor mounting plate
- 8 pole PSC ball bearing outdoor condenser fan motor

Comfort

- System supports Infinity™ Control or standard 2-stage thermostat controls

Reliability

- Puron® refrigerant - environmentally sound, won't deplete the ozone layer and low lifetime service cost.
- Front-seating service valves
- 2-stage scroll compressor
- Internal pressure relief valve
- Internal thermal overload
- Low pressure switch
- High pressure switch
- Filter drier
- Crankcase Heater standard
- Balanced refrigeration system for maximum reliability

Controls and Diagnostics

- Infinity™ control (Dedicated A,B,C,D only)
- Utility Interface Connection
- Up to 18 point diagnostic capability

Durability

WeatherArmor™ protection package:

- Solid, Durable sheet metal construction
- Steel louver coil guard
- Baked-on, complete outer coverage, powder paint

Applications

- Long-line - up to 250 feet (76.2 m) total equivalent length, up to 200 feet (60.96 m) condenser above evaporator, or up to 80 ft. (24.38 m) evaporator above condenser (See Longline Guide for more information.)
- Low ambient (down to 0°F) with complete Infinity system.

energy ENERGY STAR

This product has been designed and manufactured to meet Energy Star® criteria for energy efficiency when matched with appropriate coil components. However, proper refrigerant charge and proper air flow are critical to achieve rated capacity and efficiency. Installation of this product should follow all manufacturing refrigerant charging and air flow instructions. **Failure to confirm proper charge and air flow may reduce energy efficiency and shorten equipment life.**

* Permissible limits of the voltage range at which the unit will operate satisfactorily

† If wire is applied at ambient greater than 30°C, consult table 310–16 of the NEC (NFPA 70). The ampacity of non–metallic–sheathed cable (NM), trade name ROMEX, shall be that of 60°C conditions, per the NEC (NFPA 70) Article 336–26. If other than uncoated (no–plated), 60 or 75°C insulation, copper wire (solid wire for 10 AWG or smaller, stranded wire for larger than 10 AWG) is used, consult applicable tables of the NEC (NFPA 70).

‡ Length shown is as measured one way along wire path between unit and service panel for voltage drop not to exceed 2%.

** Time–Delay fuse.

FLA – Full Load Amps

LRA – Locked Rotor Amps

MCA – Minimum Circuit Amps

RLA – Rated Load Amps

NOTE: Control circuit is 24–V on all units and requires external power source. Copper wire must be used from service disconnect to unit. All motors/compressors contain internal overload protection.

Complies with 2010 requirements of ASHRAE Standards 90.1

A-WEIGHTED SOUND POWER (dBA)

Executive Summary

This Fire Protection Plan (FPP) has been prepared for the Ventura Ranch Farmworker Housing project (Project). This FPP evaluates and identifies the potential fire risk associated with the Project's land uses and identifies requirements for water supply, fuel modification and defensible space, fire apparatus access, building ignition and fire resistance, and fire protection systems, among other pertinent fire protection features. The purpose of this FPP is to generate and memorialize the fire safety requirements and standards of the Ventura County Fire Department (VCFD) along with Project-specific measures based on the Project site, its intended use, and its environment.

This FPP provides analysis of the Project site's fire environment and its potential impact on the Project as well as the Project's potential impact on the fire protection and suppression services of the VCFD. Requirements and recommendations herein are based on Project site-specific fire environment analysis and Project characteristics and incorporates area fire planning documents, Project site risk analysis, and standard principles of fire protection planning.

As detailed in this FPP, the Project site's fire protection approach will include redundant layering of protection methods that have been proven to reduce overall fire risk. The requirements and recommendations included herein are performance- based rather than a prescriptive, one-size-fits-all approach. The fire protection approach is designed to reduce the wildfire hazards on the site, to minimize risks associated with proposed uses, and aid the responding firefighters during an emergency. No singular measure is intended to be relied upon for the site's fire protection, but rather, a system of fire protection measures, methods, and features combine to result in enhanced fire safety, reduced fire potential, and a prepared community.

The Project is a comprehensive residential community exclusively for farmworkers and their families, located north of the city of Ventura. The community will consist of 328 one-, two- and three-bedroom apartments, along with community spaces such as two indoor community centers, a teen/adult recreational amenity (such as a basketball court), play fields, community garden, walking paths, and playgrounds, within an unincorporated area of the County of Ventura. This community will provide critical farmworker housing for Ventura County. In recent years, affordable, safe farmworker housing has been increasingly difficult to find in the county, hindering growth of the local agricultural industry and burdening local farmers and farmworkers.[1]

Development of the Project will be in three phases as detailed on the Conceptual Site Plan and Tentative Parcel Map. Phase One will consist of a total of 92 units, Phase Two will consist of 104 units, and Phase Three will consist of 132 units. Each of the three phases will be owned by a separate limited partnership.

Located at 4884 N Ventura Avenue in the unincorporated Ventura County, north of the city of Ventura, the Project is directly south of the Norway Tract, also known as the Valley Vista community. Two driveways will provide access in and out of the site onto Ventura Avenue. An emergency access only, gated road will connect the project to the Valley Vista community to the north through the extension of Floral Drive. This access will only be available in the event of an emergency.[2]

The Project will include a four lot Tentative Parcel Map of an existing 82.92-acre legal lot. The farmworker housing development will consist of three parcels of 6.11 acres, 4.81 acres and 8.66 acres. A 63.34-acre parcel will be

1 Project Summary, Jensen Design & Survey, 2025
2 Ibid

created that will remain undeveloped open space and will be designated a Conservation Subdivision lot. That lot will be owned by a Conservation Entity.[3]

The entire Project site has been designed with fire protection as a key objective. The Project site improvements are designed to facilitate emergency apparatus and personnel access throughout the Project site. Driveway and road improvements provide emergency access to every building. Water availability and flow will be consistent with requirements including fire flow and hydrant distribution required by local and state codes. These features along with the ignition resistance of all buildings, the interior fire sprinklers, and the pre-incident planning, training, and awareness will assist responding firefighters through prevention, protection, and suppression capabilities.

Based on the results of this FPP's analysis and findings, the following FPP implementation measures will be provided by the Project as part of the proposed development plan: (These measures are discussed in more detail throughout this FPP.)

1. All structures to be built in accordance with enhanced ignition-resistant construction standards based on the latest Building and Fire Codes.
2. Fire resistive landscaping per VCFD standards will be incorporated and maintained throughout the development.
3. Fire access roads will be installed and maintained to code requirements.
4. Driveways (streets), fire hydrants, and associated infrastructure will provide comprehensive access and coverage for site protection and defense.
5. Water capacity and delivery will provide for a reliable water source for operations and during emergencies requiring extended fire flow.
6. Two primary ingress/egress routes are provided from Ventura Avenue on the west with an emergency access/egress provided on the northeast side of the project.
7. Project will provide code-complying vegetation fuel modification.

[3] Ibid

1 Introduction

This Fire Protection Plan (FPP) has been prepared for the Ventura Ranch Farmworker Housing project (Project) in Ventura, California. The purpose of the FPP is to assess the potential impacts resulting from wildland fire hazards and identify the measures necessary to adequately mitigate those impacts. Additionally, the purpose of this FPP is to generate and memorialize the fire safety requirements of the Fire Authority Having Jurisdiction (FAHJ), which is the Ventura County Fire Department (VCFD). Requirements are based on site-specific characteristics, applicable code requirements, and incorporate input from the Project's applicant, project planners, engineers, and architects, as well as VCFD.

As part of the assessment, this FPP has considered the property location, topography, surrounding combustible vegetation (fuel types), climatic conditions, and fire history. This FPP addresses water supply, fire apparatus access, structural ignitability and fire resistive building features, fire protection systems and equipment, impacts to existing emergency services, defensible space, and vegetation management. The plan identifies and prioritizes areas for hazardous fuel reduction treatments and recommends the types and methods of treatment that will protect one or more at-risk communities and essential infrastructures.

The following tasks were performed toward the completion of this FPP:

- Gather Project site specific climate, terrain, and fuel data.
- Collect Project site photographs.
- Process and analyze the data using the latest GIS technology.
- Predict fire behavior using scientifically based fire behavior models, comparisons with actual wildfires in similar terrain and fuels, and experienced judgment.
- Analyze and guide design of proposed infrastructure.
- Analyze the existing emergency response capabilities.
- Assess the risk associated with the Project and the Project site.
- Prepare this FPP detailing how fire risk will be mitigated through a system of code-complying vegetation fuel modification, structural ignition resistance, and fire protection delivery systems.

Field observations were utilized to augment existing digital Project site data in generating the fire behavior models and formulating the recommendations presented in this FPP. Refer to Appendix A for Project site photographs of existing conditions.

1.1 Applicable Codes/Existing Regulations

This FPP documents the features of the Project that comply with the applicable portions of the Ventura County Building and Fire Codes, as amended and in effect at the time of this report's preparation. This FPP also documents features of the Project that do not entirely conform to the prescriptive requirements of the applicable codes. In such cases, this FPP includes project design features or fire protection measures as proposed alternative materials and methods (AM&M) that may be acceptable to the VCFD. This FPP also discusses the Project's compliance with the California Code of Regulations Title 14 and Title 24, which includes Chapter 7A of the 2022 California Building Code

(CBC). The Project would also be subject to the provisions of Section 4291 of the Public Resources Code regarding brush clearance standards around structures and the related VCFD Guidelines.

Chapter 7A of the CBC addresses reducing ember penetration into homes, a leading cause of structure loss from wildfires (California Building Standards Commission, 2019). Thus, code compliance is an important component of the requirements of this FPP, given the Project's wildland-urban interface (WUI) location that is adjacent to areas statutorily designated as a State Responsibility Area (SRA) Very High Fire Hazard Severity Zone (VHFHSZ) by the California Department of Forestry and Fire Protection (CAL FIRE). The Project site itself is designated as a Local Responsibility Area (LRA) VHFHSZ. Fire hazard designations are based on topography, vegetation, and weather, among other factors, including steep terrain, unmaintained fuels/vegetation, and WUI locations. VHFHSZs are not designated to prohibit development but do require that a higher level of fire protection is provided. Projects situated in VHFHSZs require fire hazard analysis and application of fire protection measures to create defensible communities within these WUI locations.

As described in this FPP, the Project would meet applicable code requirements for construction in these higher fire hazard areas. These codes have been developed through decades of wildfire structure save and loss evaluations to determine the causes of building loss during wildfires. The resulting fire codes now focus on mitigating former structural vulnerabilities through construction techniques and materials so that the buildings are resistant to ignitions from direct flames, heat, and embers, as indicated in the 2022 California Building Code Chapter 7A, Section 701A Scope, Purpose, and Application (California Building Standards Commission, 2019).

This FPP is consistent with the Ventura County Codes. Further, it is consistent with the California Code of Regulations Titles 14 and 24 and the 2022 California Fire Code (CFC) and 2022 Building Code (CBC). Chapter 7A of the California Building Code (CBC) focuses primarily on preventing ember penetration into homes, a leading cause of structure loss from wildfires; thus, it is an important component of the requirements of this FPP.

The Project will also be compliant with the following codes and regulations:

- 2022 California Building Code, Ch. 7A – Materials and Construction Methods for Exterior Wildfire Exposure: minimum standards for a new building located in a WUI area to resist the intrusion of flame or burning embers projected by a vegetation fire.
- 2022 California Fire Code, Chapter 49 – Requirements for Wildland-Urban Interface Fire Areas: minimum standards to increase the ability of a building to resist the intrusion of flame or burning embers being projected by a vegetation fire.
- 2022 California Code of Regulations, Title 14, Div. 1.5, Ch. 7, Sub-Ch. 2 – SRA/VHFHSZ Fire Safe Regulations: minimum wildfire protection standards in conjunction with building, construction and development in the SRA and VHFHSZ.
- California Public Resources Code, Div. 4, Part 2, Ch. 3, Sec. 4290: minimum fire safety standards related to defensible space in Hazardous Fire Areas; Sec. 4291: Defensible space maintenance on Mountainous, Forest-, Brush- and Grass-Covered Lands.
- California Government Code, Title 5, Div. 1, Part 1, Ch. 6.8, Sec. 51175-51189: Very High Fire Hazard Severity Zones.
- California Government Code, Title 7, Div. 2, Ch. 4 Sec. 66474.02: requirements for tentative map approval in a very high fire hazard severity zone.
- 2022 Ventura County Building Code: 2022 California Building Code as adopted with amendments.

- **2022 Ventura County Fire Code:** 2022 California Fire Code as adopted with amendments.
- **Ventura County Fire Department Guidelines:** guidelines regarding fuel modification zones, defensible space, landscaping, fire protection plans, and other related topics (410, 412, 416, 418, 420, 423, 424, 515).

1.2 Project Summary

1.2.1 Location

The Project site is located at 4884 N Ventura Avenue in the unincorporated Ventura County, north of the city of Ventura. It is directly south of the Norway Tract, also known as the Valley Vista community. Two driveways will provide access in and out of the site onto Ventura Avenue. An emergency access only, gated road will connect the project to the Valley Vista community to the north through the extension of Floral Drive. This access will only be available in the event of an emergency.[4]

The Project is situated on two of four contiguous parcels (Assessor Parcel Numbers (APNs) 063-0-110-090; -145; -065; - 035). The farmworker housing development will consist of three parcels of 6.11 acres, 4.81 acres and 8.66 acres. A 63.34-acre parcel will be created that will remain undeveloped open space and will be designated a Conservation Subdivision lot. That lot will be owned by a Conservation Entity.

Surrounding land uses include a residential community to the north, agricultural open space to the east and south and Ventura Avenue, Ojai Freeway and vacant land to the west. The entirety of the property lies within a Local Responsibility Area (LRA) Very High Fire Hazard Severity Zone (VHFHSZ), as statutorily designated by the CVFD and CAL FIRE.

1.2.2 Existing Land Use

The existing on-site land use of the proposed development is currently vacant agricultural land and a single family dwelling with some outbuildings.

1.2.3 Project Description

The Project is a comprehensive residential community exclusively for farmworkers and their families, located north of the city of Ventura. The community will consist of 328 apartments, along with community spaces such as two indoor community centers, a teen/adult recreational amenity (such as a basketball court), play fields, community garden, walking paths, and playgrounds, within an unincorporated area of the County of Ventura. This community will provide critical farmworker housing for Ventura County. In recent years, affordable, safe farmworker housing has been increasingly difficult to find in the county, hindering growth of the local agricultural industry and burdening local farmers and farmworkers.[5]

The Project will be developed in three phases as detailed on the Conceptual Site Plan and Tentative Parcel Map. Phase One will consist of a total of 92 units, Phase Two will consist of 104 units, and Phase Three will consist of 132 units. Each of the three phases will be owned by a separate limited partnership.

2 Project Site Risk Analysis

2.1 Field Assessment

After review of the available information, including topography, vegetation types, fire history, and the Project's development footprint, a Dudek Fire Protection Planner conducted a site evaluation on April 30, 2025, in order to confirm/acquire site information, document existing site conditions, and to determine potential actions for addressing the protection of the Project's structures. While on site, Dudek's Fire Planner assessed the area's topography, vegetation and fuel loading, surrounding land use and general susceptibility to wildfire. Among the field tasks that were completed included:

- Vegetation estimates and mapping refinements
- Fuel load analysis
- Topographic features documentation
- Surrounding land use
- Photograph documentation
- Confirmation/verification of hazard assumptions
- Ingress/egress documentation.
- Nearby Fire Station reconnaissance

Field observations were utilized to augment existing Project site data in generating the fire behavior models and formulating the recommendations detailed in this report.

2.2 Project Site Characteristics and Fire Environment

Fire environments are dynamic systems and include many types of environmental factors and site characteristics. Fires can occur in any environment where conditions are conducive to ignition and fire movement. Areas of naturally vegetated open space are typically comprised of conditions that may be favorable to wildfire spread. The three major components of fire environment are topography, vegetation (fuels), and weather. The state of each of these components and their interactions with each other determines the potential characteristics and behavior of a fire at any given moment. It is important to note that wildland fire may transition to urban fire if structures are receptive to ignition. Structure ignition depends on a variety of factors and can be prevented through a layered system of protective features including fire resistive landscapes directly adjacent the structure(s), application of known ignition resistive materials and methods, and suitable infrastructure for firefighting purposes. Understanding the existing wildland vegetation and urban fuel conditions on and adjacent to the site is necessary to understand the potential for fire within and around the Project site.

The following sections discuss the characteristics of the Project area at a regional scale. Evaluating conditions at this macro-scale provides a better understanding of the regional fire environment, which represents the fuel bed for wildfires that may ignite in the vicinity of, and burn toward, the Project's planned and maintained fire buffers, landscapes, and ignition-resistant structures.

2.2.1 Topography

Topography influences fire risk by affecting fire spread rates. Typically, steep terrain results in faster fire spread up-slope and slower spread down-slope. Terrain that forms a funneling effect on the landscape can result in especially intense fire behavior. Conversely, flat terrain tends to have little effect on fire spread, resulting in fires that are driven by vegetation and wind.

Topography of the Project consists primarily of flat terrain with a slight gradient to the west. Elevations within the Project site range from about 200 to 250 feet above mean sea level (AMSL). East of the Project site (open space parcels) the topography includes steeper slopes with ravines; elevations range from 250 to 700 feet AMSL.

The Topatopa Mountains are located further east of the Project site within the Los Padres National Forest and the ecoregion known as the California montane chaparral and woodlands.

A regional topographic feature that may present a fire spread facilitator is the Ventura River (immediately west of the Project site), which may serve to funnel or channel winds, thus increasing their velocity and potential for influencing wildfire behavior.

2.2.2 Climate

The Project site, like much of southern California, is influenced by prevailing wind patterns. Prevailing winds are winds that blow from a single direction over a specific area of the Earth. The prevailing winds for the Project site typically are from the west averaging about six miles per hour (mph), but the presence of the Pacific Ocean can cause a diurnal wind pattern known as the land/sea breeze system. In the fall and winter, winds are from the north, averaging eight mph. Surface winds can also be influenced locally by topography and slope variations. The highest wind velocities are associated with downslope, canyon, and Santa Ana winds. The Project site includes topography that is subject to periodic extreme fire weather conditions that occur throughout southern California and Ventura County.

Wet winters and dry summers with mild seasonal changes characterize the southern California climate. This climate pattern is occasionally interrupted by extreme periods of hot weather, winter storms, or dry, northeasterly Santa Ana winds. The project area has daily highs in the summer and early fall months (June–October) exceeding 73°F. Precipitation typically occurs between October and April with average rainfall of 14 inches, per year (Weatherspark[6]).

From a regional perspective, the fire risk in southern California can be divided into three distinct “seasons” (Nichols et al. 2011, Baltar et al. 2014). The first season, the most active season and covering the summer months, extends from late May to late September. This is followed by an intense fall season characterized by fewer but larger fires. This season begins late September and continues until early November. The remaining months, November to late May cover the mostly dormant, winter season. Mensing et al. (1999) and Keeley and Zedler (2009) found that large fires in the region consistently occur at the end of wet periods and the beginning of droughts.

Typically, the highest fire danger in southern California coincides with Santa Ana winds. The Santa Ana wind conditions are a reversal of the prevailing southwesterly winds that usually occur on a region-wide basis near the end of fire season during late summer and early fall. Santa Ana winds are dry, warm, gusty foehn winds that flow from the high desert in the Great Basin (Nevada, western Utah and eastern California) through the mountain passes

6 https://weatherspark.com/y/1448/Average-Weather-in-Ventura-California-United-States-Year-Round#google_vignette

and canyons toward the Pacific Ocean. As they converge through the canyons and narrow passes, their velocities increase, gradually dissipating as they spread across wide valley floors. Localized wind patterns are strongly affected by both regional and local topography.

2.2.3 Vegetation

2.2.3.1 Fuels (Vegetation)

Vegetation type mapping is useful for fire planning, because it enables each vegetation community to be assigned a fuel model, which is used in a modeling program to predict fire behavior characteristics, as discussed in Section 3.1, Fire Behavior Modeling.

Vegetation on site is comprised of ruderal forbs and cut stalks from past agricultural uses. There are no active agricultural practices currently taking place on site. The area proposed for development and within the Project grading limits will be converted from agricultural use to residential structures, roadways and landscaped vegetation following project completion. The parcels east of the project site will remain as natural open space as will the Topatopa Mountains, which have a typical chaparral and woodland mix of Chamise, Manzanita, and Scrub Oak vegetation (World Wildlife Fund, 2022).

Following build-out, irrigated landscape vegetation associated with fuel modification zones (FMZ) is expected to cover the Project site, extending approximately 100 horizontal feet from each of the structures. An additional 100 feet of thinned, non-irrigated vegetative fuel modification will be provided for the Project as a VCFD approved standard mitigation for the reduced distance between fire apparatus access points to the Project. The provided FMZ areas will be maintained in order to comply with the final approved Fuel Modification Plan and VCFD's Standard 515.

2.2.3.2 Vegetation Dynamics

The vegetation characteristics described above are used to model fire behavior, discussed in Sections 3.2 and 3.3 of this FPP. Variations in vegetative cover type and species composition have a direct effect on fire behavior. Some plant communities and their associated plant species have increased flammability based on plant physiology (resin content), biological function (flowering, retention of dead plant material), physical structure (bark thickness, leaf size, branching patterns), and overall fuel loading. For example, non-native grass dominated plant communities become seasonally prone to ignition and produce lower intensity, higher spread rate fires. In comparison, sage scrub can produce higher heat intensity and higher flame lengths under strong, dry wind patterns, but does not typically ignite or spread as quickly as light, flashy grass fuels.

This concept is a key component in the overall establishment and maintenance of the proposed fuel modification zones on the Project site. The fuel modification zones on the Project site will consist of paved areas and irrigated and maintained landscapes, which results in reduced fire ignition, spread rates, and intensity.

2.2.4 Fire History

Fire history is an important component of an FPP. Fire history data provides valuable information regarding fire spread, fire frequency, most vulnerable areas, and significant ignition sources, amongst others. In turn, this understanding of why fires occur in an area and how they typically spread can then be used for pre-planning and designing defensible communities.

Fire history represented in this FPP uses the Fire and Resource Assessment Program (FRAP) database. FRAP summarizes fire perimeter data dating to the late 1800s, but which is incomplete due to the fact that it generally includes fires over 10 acres in size and has incomplete perimeter data, especially for the first half of the 20th century (Syphard and Keeley 2016). However, the data does provide a summary of recorded fires and can be used to show whether large fires have occurred in the Project area, which indicates whether they may be possible in the future.

According to available data from the CAL FIRE in the FRAP database[7], 67 fires have burned in the vicinity of the Project site since the beginning of the historical fire data record. Recorded wildfires within a 5-mile radius range from one (1) acre to 281,791 acres (2017 Thomas Fire) with an average fire size is 6,672 acres (2,503 when not including the Thomas Fire). Only one fire has burned on the Project site – the 2017 Thomas Fire – which burned about 0.02 acres in the southeast corner. Fire history for the general vicinity of the Project site is illustrated in the map in Appendix B (Project Vicinity Fire History Map).

Based on an analysis of the CAL FIRE FRAP fire history data set, specifically the years in which the fires burned, the average interval between wildfires in the area, including areas up to roughly five miles from the Project site, was calculated to be 1.6 years with intervals ranging between zero and 14 years. Based on this analysis, it is expected that a wildfire event that could impact the Project may occur, if weather conditions coincide, roughly every two years with the realistic possibility of shorter or longer interval occurrences, as observed in the fire history records.

[7] Based on polygon GIS data from CAL FIRE's FRAP, which includes data from CAL FIRE, USDA Forest Service Region 5, BLM, NPS, Contract Counties and other agencies. The data set is a comprehensive fire perimeter GIS layer for public and private lands throughout the state and covers fires 10 acres and greater between 1878–2023.

3 Anticipated Fire Behavior

3.1 Fire Behavior Modeling

Following field data collection efforts and available data analysis, fire behavior modeling was conducted to document the type and intensity of fire that would be expected adjacent to the Project site given characteristic site features such as topography, vegetation, and weather. Dudek utilized BehavePlus modeling program (Andrews, Bevins, and Seli 2008) to analyze potential fire behavior on and adjacent to the Project site, with assumptions made for the pre- and post-Project slope and fuel conditions. Results are provided below.

3.2 Fire Behavior Modeling Analysis

An analysis utilizing the BehavePlus modeling program was conducted to evaluate fire behavior variables and to objectively predict flame lengths, intensities, and spread rates for five modeling scenarios. These fire scenarios incorporated observed fuel types representing the dominant on-site and off-site vegetation on adjacent land to the east, south and west, in addition to slope gradients, and wind and fuel moisture values for both the 50th percentile weather (summer, onshore winds) and the 97th percentile weather (fall, offshore winds). Modeling scenario locations were selected to better understand different fire behavior that may be experienced on or adjacent to the Project site.

Vegetation types, which were derived from available resource materials and confirmed during the field assessment for the Project site, were classified into a fuel model. Fuel models are simply tools to help fire experts realistically estimate fire behavior for a vegetation type. Fuel models are selected by their vegetation type; fuel stratum most likely to carry the fire; and depth and compactness of the fuels. Fire behavior modeling was conducted for vegetative types that surround the proposed development. Fuel models were selected from *Standard Fire Behavior Fuel Models: a Comprehensive Set for Use with Rothermel's Surface Fire Spread Model* (Scott and Burgan 2005). Fuel models were also assigned to the perimeter fuel management areas to illustrate post-Project fire behavior changes. Based on the anticipated pre- and post-Project vegetation conditions, seven different fuel models were used in the fire behavior modeling effort presented herein. Fuel model attributes are summarized in Table 1.

Table 1. Fuel Models Used for Fire Behavior Modeling

Fuel Model Type	Title	Description	Application (Behave Run)
GR1	Grass–short, sparse, dry climate	Grass is sparse or discontinuous, short, with an average depth of about one foot. Spread rate low; flame length low.	Treated grassland
GR4	Moderate load dry climate grass	Moderately coarse continuous grass. Spread rate very high; flame length high.	Grassland
GS1	Shrubs and Grass–Low Load, Arid Climate	Shrubs are about one foot high; grass load is low. Spread rate moderate; flame length low.	Treated roadside vegetation
GS2	Moderate load dry climate grass-shrub	Moderate shrub fuel load, moderate grass load. Spread rate high; flame length moderate.	Coastal sage scrub

Table 1. Fuel Models Used for Fire Behavior Modeling

Fuel Model Type	Title	Description	Application (Behave Run)
SH1	Low load dry climate shrub	Low shrub fuel load; some grass may be present. Spread rate very low; flame length very low.	Treated coastal sage scrub
SH2	Moderate load dry climate shrub	Moderate fuel load, no grass fuel present. Spread rate low; flame length low.	Coastal sage scrub/chaparral
TL6	Moderate load broadleaf litter	Fuel bed composed of broadleaf (hardwood) litter. Moderate load, less compact. Spread rate moderate; flame length low.	Eucalyptus windrow
FM8	Irrigated landscaping/ compact litter	The primary carrier of fire is landscaping litter, though small amounts of fine dead fuel may be present. The landscaping material is generally hydrated with high moisture content. Spread rate low; flame length low.	Irrigated landscaping
NB1	Urban or suburban development	Insufficient wildland fuel to carry wildland fire.	Paved roadway, parking, hardscape

Table 2 summarizes the weather and wind input variables used in the BehavePlus modeling process.

Table 2. Fuel Moisture and Wind Inputs

Variable	Weather Condition (97th Percentile)
1h Moisture	2%
10h Moisture	3%
100h Moisture	5%
Live Herbaceous Moisture	70%
Live Woody Moisture	50%
20-foot Wind Speed (mph)	40
Wind Adjustment Factor	0.4

3.3 Fire Behavior Modeling Results

The results of fire behavior modeling analysis for pre- and post-project conditions are presented in Tables 3 and 4, respectively. Identification of modeling run (fire scenarios) locations is presented graphically in Figure 4, Wildfire Behavior Modeling Scenarios.

Fire Scenario locations and descriptions:

- Scenario 1. Fire flaming front approaching from the northeast towards the eastern boundary of the Norway Tract (Valley Vista community) with northeastern winds.
  - *Existing conditions:* undeveloped land with annual grassland and fuel treatment (Fuel Models GR4, GR1).
  - *Post-development conditions:* includes the fuel treatment recommendations (Fuel Model GR1).

- Scenario 2. Fire flaming front approaching from the northeast towards the eastern boundary of the Norway Tract (Valley Vista community) with northeastern winds.
  - ***Existing conditions:*** undeveloped land with coastal sage scrub and avocado orchard (Fuel Models GS2, FM8).
  - ***Post-development conditions:*** includes the fuel treatment recommendations (Fuel Model GS1, FM8).
- Scenario 3. Fire flaming front approaching from the northeast towards the eastern boundary of the project with northeastern winds.
  - ***Existing conditions:*** undeveloped land with coastal sage scrub/chaparral and avocado orchard (Fuel Model SH2, FM8).
  - ***Post-development conditions:*** includes the fuel treatment recommendations, irrigated landscaping and paved roadway (Fuel Model SH1,FM8, NB1).
- Scenario 4. Fire flaming front approaching from the south towards the southern boundary of the project with south winds.
  - ***Existing conditions:*** adjacent fallow agricultural field, harvested agriculture field (Fuel Models GR2, GR1).
  - ***Post-development conditions:*** includes the fuel treatment recommendations, irrigated landscaping and paved roadway (Fuel Models GR2. FM8, NB1).
- Scenario 5. Fire flaming front approaching from the southwest towards the western boundary of the project with southwestern winds.
  - ***Existing conditions:*** freeway, grassland, paved roadway and eucalyptus windrow (Fuel Models NB1, GR4, TL6).
  - ***Post-development conditions:*** includes the freeway, grassland, paved roadway and irrigated landscaping (Fuel Models NB1, GR4, FM8).

The results presented in Tables 3 and 4 depict values based on inputs to the BehavePlus modeling program reflecting a "moment in time" and are not intended to capture changing fire behavior as it moves across a landscape. Changes in slope, weather, or pockets of different fuel types are not accounted for in this analysis, but the models provide a worst-case wildfire behavior condition as part of a conservative approach. For planning purposes, the averaged worst-case fire behavior is the most useful information for conservative fuel modification design. Model results should be used as a basis for planning only, as actual fire behavior for a given location would be affected by many factors, including unique weather patterns, small-scale topographic variations, or changing vegetation patterns.

3.4 Fire Behavior Summary

3.4.1 Existing Conditions

The results of fire behavior modeling analysis for pre- and post-Project conditions are presented in Tables 3 and 4, respectively. Identification of modeling run (fire scenarios) locations is presented graphically in Figure 4, Wildfire Behavior Modeling Scenarios.

As presented in Table 3, Fire Behavior Results for Existing Conditions, Dudek conducted modeling of the Project site for pre-development fuel conditions for the Project. The vegetation fuels include grassland, coastal sage shrub,

and both active and fallow agricultural vegetation. For modeling the pre-development condition, fuel model assignments were classified as Fuel Model GR1 for treated grassland, Fuel Model GR2 for agricultural vegetation, Fuel Model GR4 for untreated grassland, Fuel Model GS2 for sage scrub, Fuel Model NB1 for the streets and walkways, and Fuel Model TL6 for Eucalyptus windrow.

As presented in the Wildfire Behavior Modeling Scenarios figure, wildfire behavior in grassland, modeled as GR4, would exhibit the most intense fire behavior (refer to Table 3, Fire Behavior Results for Existing Conditions). A worst-case fire under gusty Santa Ana winds and low fuel moistures is expected to be fast moving modeled at advancing 4.7 mph from east to west. Flame length values were modeled at 20 feet in untreated native grass on lands adjacent to the property. Ember spotting is projected to occur up to 1.2 miles from the flaming front.

Table 3. Fire Behavior Results for Existing Conditions

Fire Scenarios	Spread Rate (mph)	Fireline Intensity (BTU/ft/sec)	Flame Length (ft)	Spotting Distance[1] (mi)
Scenario 1: 30% slope, 40 mph wind from NE				
Fuel Model GR4 – grassland	4.7	3840	20.0	1.2
Fuel Model GR1 – treated grassland	0.3	37	2.4	0.3
Scenario 2: 30% slope, 40 mph wind from NE				
Fuel Model GS2 – coastal sage shrub	2.3	1899	14.5	1.0
Fuel Model FM8 – avocado orchard	0.1	46	2.6	0.3
Scenario 3: 30% slopes, 40 mph wind from NE				
Fuel Model SH2 – coastal sage scrub/chaparral	0.8	1728	13.9	0.9
Fuel Model FM8 – avocado orchard	0.1	46	2.6	0.3
Scenario 4: 5% slope, 20 mph wind from S				
Fuel Model GR2 – fallow agricultural field	0.9	360	6.8	0.3
Fuel Model GR1 – harvested agricultural field	0.3	37	2.4	0.2
Scenario 5: 10% slope, 20 mph wind from SW				
Fuel Model NB1 – paved street	0	0	0	0
Fuel Model GR4 – grassland	1.8	1450	12.8	0.5
Fuel Model TL6 – eucalyptus windrow	0.2	189	5.0	0.3

Note:
[1] Spotting distance from a wind driven surface fire.

3.4.2 Post-Project Conditions

As presented in Table 4, Fire Behavior Results for Post-Project Conditions, Dudek conducted modeling of the Project site for post-development fuel conditions. The fuel modification area includes paved roadways, parking lots and irrigated landscaping throughout the Project. For modeling the post-development condition, fuel model assignments were re-classified as Fuel Model 8 for the irrigated landscaping, Fuel Model GS1 for maintained native shrubs, and Fuel Model NB1 for the streets and walkways. Fuel model assignments for all other areas remained the same as those classified for the existing condition.

Table 4. Fire Behavior Results for Post-Project Conditions

Scenario	Spread Rate (mph)	Fireline Intensity (BTU/ft/sec)	Flame Length (ft)	Spotting Distance[1] (mi)
Scenario 1: 30% slope, 40 mph wind from NE				
Fuel Model GR1 – maintained grassland for fuel modification	0.3	37	2.4	0.3
Scenario 2: 30% slope, 40 mph wind from NE				
Fuel Model GS1 – maintained shrubs for fuel modification	1.6	745	9.4	0.7
Scenario 3: 30% slope, 40 mph winds from NE				
Fuel Model SH1 – maintained shrubs for fuel modification	1.0	569	8.3	0.6
Fuel Model NB1 – paved roadway	0	0	0	0
Fuel Model 8 – Irrigated landscaping	0.1	46	2.6	0.3
Scenario 4: 5% slope, 20 mph wind from S				
Fuel Model NB1 – paved roadway	0	0	0	0
Fuel Model 8 – Irrigated landscaping	0.1	26	2.0	0.2
Scenario 5: 5% slope, 20 mph wind from SW				
Fuel Model NB1 – paved roadway	0	0	0	0
Fuel Model GR4 – grassland	1.8	1450	12.8	0.5
Fuel Model 8 – Irrigated landscaping	0.1	26	2.0	0.2

Note:
[1] Spotting distance from a wind driven surface fire.

Fire behavior modeling Scenarios 1, 2, and 3 anticipate a wildfire approaching from north and east of the Project site advancing toward the eastern boundary of the Project through various vegetation fuels on 30% slopes with 40 mph winds from the northeast. The worst case is a wildfire in grassland fuels with existing conditions advancing at 4.7 mph with 20-foot flame lengths and ember spotting to a distance of 1.2 miles from the front of the fire. It is anticipated that the fire will decrease in intensity when it reaches the Project site and encounters less fuel, which is currently ruderal forbs and cut stalks from past agricultural uses. Wildfire conditions significantly improve under Scenarios 1, 2, and 3 when fuel modification zones are created and maintained. Post-Project conditions will result in a wildfire advancing 0.3 mph with 2.4-foot flame lengths in maintained grasses and 9.4 flame lengths in maintained shrubs with ember spotting to a distance of 0.6 miles from the front of the fire.

Fire behavior modeling Scenario 4 anticipates a wildfire approaching from south of the Project boundary on a 5% slope with wind from the south at 20 mph and burning in fallow and harvested agricultural vegetation fuels prior to arriving at the Project site. The rate of spread is less than 1 mph with flame lengths of 6.8 feet and ember spotting to a distance of 0.3 miles from the front of the fire. Existing fuel conditions on the Project site are similar to the fuel conditions south of the Project site. Fire behavior on the Project site under existing conditions is expected to be about the same as fire behavior in the area south of the Project. Wildfire conditions also significantly improve on the Project site under Scenario 4 when fuel modification zones are established within the Project boundary. Post-Project conditions will result in a wildfire advancing 0.1 mph with 2-foot flame lengths in irrigated landscaping with ember spotting to a distance of 0.2 miles from the front of the fire.

Fire behavior modeling Scenario 5 is a wildfire approaching from the southwest towards the western boundary of the Project on a 10% slope with winds from the southwest at 20 mph and burning in grasses and agricultural fuels prior to arriving at the Project site. The rate of spread is 1.8 mph with flame lengths of 12.8 feet and ember spotting to a distance of 0.5 miles. Fire behavior on the Project site under existing conditions is expected to be about the same as fire behavior in the area west and southwest of the Project. Wildfire conditions under Scenario 5 are relatively unchanged when fuel modification zones are established within the Project boundary.

The fuel modification areas within the Project site experienced a significant reduction in flame length and wildfire intensity. Post-Project fuel modification results in flame lengths that are less than half of the existing conditions for Scenarios 1, 2, and 3 where the wildfire is approaching from the north and east. Post-Project ember spotting for Scenarios 1, 2, and 3 has been reduced by half as compared to existing conditions. Anticipated fire behavior is significantly improved with post-Project fuel modification for a Scenario 4 wildfire approaching from the southwest. Flame lengths are reduced to less than one-third of those produced by existing conditions while ember spotting is reduced by half.

The results presented in Tables 3 and 4 depict values based on inputs to the BehavePlus modeling program and are not intended to capture changing fire behavior as it moves across a landscape. Changes in slope, weather, or pockets of different fuel types are not accounted for in this analysis, but the models provide a worst-case wildfire behavior condition as part of a conservative approach. For planning purposes, the averaged worst-case fire behavior is the most useful information for conservative fuel modification design. Model results should be used as a basis for planning only, as actual fire behavior for a given location would be affected by many factors, including unique weather patterns, small-scale topographic variations, or changing vegetation patterns.

3.5 Project Area Fire Risk Assessment

Wildland fires are a common natural hazard in most of southern California with a long and extensive history. Southern California landscapes include a diverse range of plant communities, including vast tracts of grasslands and shrublands. Wildfire in this Mediterranean-type ecosystem ultimately affects the structure and functions of vegetation communities (Keeley 1984) and will continue to have a substantial and recurring role (Keeley and Fotheringham 2003). Supporting this are the facts that 1) native landscapes, from forest to grasslands, become highly flammable each fall and 2) the climate of southern California has been characterized by fire climatologists as the worst fire climate in the United States (Keeley 2004) with high winds (Santa Ana) occurring during autumn after a six-month drought period each year. Based on this research, the anticipated growing population of WUI areas, and the regions fire history, it can be anticipated that periodic wildfires may start on, burn onto, or spot into the Project site. The most common type of fire anticipated in the vicinity of the Project Area is a wind-driven fire from the north/northeast moving through the annual grasses and sage scrub shrubs found on the lands adjacent to the Project.

Therefore, it will be critical that the latest fire protection technologies, developed through intensive research and real-world wildfire observations and findings by fire professionals, for both ignition resistant construction and for creating defensible space in the ever-expanding WUI areas, are implemented and enforced. The Project, once developed, would not facilitate wildfire spread and would reduce projected flame lengths to levels that would be manageable by firefighting resources for protecting the Project site's structures, especially given the ignition resistance of the structures and the planned ongoing maintenance of the entire Project site landscape.

Table 3. Fire Behavior Results for Existing Conditions

Fire Scenarios	Spread Rate (mph)	Fireline Intensity (BTU/ft/sec)	Flame Length (ft)	Spotting Distance[1] (mi)
Scenario 1: 30% slope, 40 mph wind from NE				
Fuel Model GR4 – grassland	4.7	3840	20.0	1.2
Fuel Model GR1 – treated grassland	0.3	37	2.4	0.3
Scenario 2: 30% slope, 40 mph wind from NE				
Fuel Model GS2 – coastal sage shrub	2.3	1899	14.5	1.0
Fuel Model FM8 – avocado orchard	0.1	46	2.6	0.3

4 Emergency Response and Service

4.1 Emergency Response

The VCFD jurisdiction covers approximately 848 square miles in size and has an estimated population of 840,000. VCFD responds to fires, medical emergencies, traffic accidents, land and water rescues, hazardous materials calls, environmental hazards, and a variety of public service requests. VCFD provides emergency and non-emergency services to all unincorporated areas in Ventura County along with the cities of Ojai, Port Hueneme, Moorpark, Camarillo, Santa Paula, Simi Valley, and Thousand Oaks.[8] In 2023, VCFD responded to 53,661 calls for service, including 41,077 medical emergencies, 3,249 rescues, 1,191 fires and thousands of other urgent requests for assistance for an average of 147 responses each day.[9]

The VCFD currently operates 34 Fire Stations, two of which are analyzed herein due to their proximity to the Project site and could respond to an incident at the Project site (Stations 22 and 23). Primary response would be from Station 23, with Station 22 responding as necessary. Fire Station 23 houses five firefighters who staff Medic Engine 23, staffed by three personnel, and Rescue 23, staffed by two personnel. The station and its resources provide firefighting, advanced life support, and heavy rescue services to the Oak View and Casitas Springs areas of Ventura County in addition to supporting emergency operations throughout Ojai Valley. Fire Station 22 houses three firefighters who cross-staff Engine 22, Brush Engine 322, and Utility 22.[10] Mutual aid, automatic aid and other agreements with surrounding fire departments enable VCFD to provide the fastest and highest level of service.[11] Ventura City Fire Station 1 may be available to respond to the Project site as a mutual aid resource. This station houses three firefighters who staff a paramedic engine.[12]

Table 5 (Fire Department Responding Stations Summary) presents a summary of the location, fire apparatus equipment, staffing levels, maximum travel distance, and estimated travel time for the stations that may respond to a fire or medical emergency at the Project site. Travel distances are derived from Google road data while travel times are calculated applying the nationally recognized RAND Corporation formula used by the Insurance Services Office (ISO) Public Protection Classification Program's Response Time Standard: (T=0.65 + 1.7(D), where T=time and D=distance). The response travel time formula discounts speed for intersections, vehicle deceleration and acceleration, and does not include turnout time.

Table 5. Fire Department Responding Stations Summary

Station	Location	Equipment	Staffing	Maximum Travel Distance	Travel Time**
Station 23	15 Kunkle St., Oak View, California	- (1) Paramedic Engine Co. - (1) Rescue	On-Duty: 5	5.0 mi.*	9.2minutes*

12 Ventura City Fire Department. https://www.cityofventura.ca.gov/1654/Fire-Stations

Table 5. Fire Department Responding Stations Summary

Station	Location	Equipment	Staffing	Maximum Travel Distance	Travel Time**
Station 22	466 S. La Luna Ave., Ojai, California	- (1) Engine Co. - (1) Brush Engine - (1) Utility	On-Duty: 3	8.7 mi.*	15.4 minutes*
Ventura City Station 1	717 N. Ventura Ave Ventura, California 93001	- (1) Paramedic Engine Co.	On duty: 3	3.1 mi.*	5.9 minutes*

Notes:
* Distance measured to entrance of the Project site at 4884 N. Ventura Ave.
** Assumes travel to the project entrance, and application of the ISO formula, T=0.65+1.7(Distance), a 35 mph travel speed, and does not include turnout time.

Based on the Project site location in relation to existing VCFD stations, travel time to the site for the first responding engine from Station 23 is approximately 9.2 minutes to the main project entrance. Travel to the furthest occupied point of the development may require an additional 30-60 seconds to navigate the quarter-mile distance that includes two roundabouts. A secondary response from Station 22 would arrive in just over 15 minutes.

National Fire Protection Association Standard 1710, *Standard for the Organization and Deployment of Fire Suppression Operations, Emergency Medical Operations, and Special Operations to the Public by Career Fire Departments*, establishes response time standards for fire and medical emergency incidents. Local fire departments use these standards to establish response time goals. Response time is the total time from when a 9-1-1 call is received until the first emergency responders arrive at the location of the incident. Response time includes 9-1-1 call processing time; the time required for emergency responders to put on any protective clothing needed and leave the station, which is known as turnout time; and travel time. NFPA 1710 allows for 1.15 minutes for call processing time and 1.33 minutes for turnout time.[13]

The VCFD has a response time goal of 8.5 minutes for Suburban areas 90% of the time and 12 minutes for Rural areas 90% of the time.[14] The Project is located in a rural area. With an anticipated travel time of 9.2 minutes for the nearest VCFD fire engine and 2.48 minutes for call processing and turnout time, the total expected response time to the Project is 11.68 minutes, which is within the VCFD response time goal for a facility in a rural location.

It is common for rural areas to have longer response times than urban and suburban areas. For projects such as this one, it is vitally important for the Project to include all required and recommended construction materials and methods, fire protection systems, and vegetation fuel reduction through the use of FMZs. All of these elements will provide the Project and residents with a high degree of wildfire safety and protection.

13 National Fire Protection Association Standard 1710, 2020 edition.
14 Ventura County Fire Department. Public records request response, May 19, 2025.

4.2 Estimated Calls and Demand for Service from the Project

The VCFD responded to 53,661 total calls for service in 2023, the most recent year for which data is available.[15] The total population served by VCFD is approximately 840,000, resulting in a per capita call volume of roughly 0.06. Based on the proposed development plans for 328 apartments with a mix of one-, two-, and three-bedroom units, the Project is estimated to add 820 residents at full occupancy.[16] With a per capita call volume of 0.06, the Project is estimated to generate 49 calls for service to the VCFD per year at build out and full occupancy, which is a 0.1% increase in call volume when compared to the total calls for service in 2023. Most of the calls for service are expected to be medical-related calls, consistent with typical emergency call statistics.

Service level requirements are not expected to be significantly impacted by the Project. VCFD's busiest stations, which do not have additional responses from a Battalion Chief, average 12.5 calls per day. Station 23 averaged nearly 3 calls per day and Station 22 averaged nearly 4 calls per day.[17] An additional 49 calls for service per year equates to nearly 1 call per week. It is anticipated that most of the calls for service from the Project area will be handled by Medic Engine 23 and Rescue 23 responding from Station 23. The Project will not significantly increase the average daily call volume for Station 23.

15 Ventura County Fire Department. https://s45897.pcdn.co/wp-content/uploads/2024/04/AnnualReport2023.pdf

16 US Census data reports that Ventura Couty has an average household size of 2.97 people. With the Project being limited to dwelling units with 1-3 bedrooms, this report estimates that the average household size for the proposed dwelling units will be 2.5 people.

17 Ventura County Fire Department. Total Responses per VCFD Station, 2023-2024.

INTENTIONALLY LEFT BLANK

5 Fire Safety Requirements- Infrastructure, Building Ignition Resistance, And Defensible Space

The VCFD Fire Code and 2022 CFC and 2022 CBC (adopted by reference with several modifications) governs the building, infrastructure, and defensible space requirements detailed in this FPP. The Project will meet applicable codes or will provide alternative materials and/or methods (AM&M), if warranted. The following summaries highlight important fire protection features.

Prior to bringing combustible materials onto the Project site, utilities shall be in place, fire hydrants operational, an approved all-weather roadway, or an approved road surface alternative in place, and interim fuel modification zones established and approved.

5.1 Roads

5.1.1 Primary/Fire Access

The Project would involve the construction of new structures, roadways, and would generate new trips to and from the Project site. The Project site's access, including road widths and connectivity, will comply with the County's development standards and VCFD Fire Apparatus Access Standard 501 with the exception of meeting the separation requirement of the two points of access that are required for projects in a Very High Fire Hazard Severity Zone, as discussed in more detail below. Additionally, an adequate water supply and approved paved access roadways shall be installed prior to any combustibles on site and will include:

- Access to the Project site will be provided via two points of connection to Ventura Avenue that are separated by approximately 300 feet. Both of these roadways will be constructed as part of the Phase One development and remain accessible throughout all three phases of development. An additional emergency only access/egress will be available at the northeast corner of the development with the connection of Floral Drive to the existing Norway Tract community to the north as part of the Phase Three development. This additional roadway will serve both the Ventura Ranch community and the Norway Tract community, as not all emergencies are fire related.
- The VCFD requires projects located in a Very High Fire Hazard Severity Zone to have two points of access that are separated by a minimum of 1,000 feet. In lieu of providing the minimum separation, VCFD requires an additional 100 feet of vegetation fuel modification for a total of 200 feet.
- Proposed on-site interior streets will facilitate access throughout the site to meet fire department access requirements to each structure. All primary circulation roads comply with two-way access road standards and are capable of supporting an imposed load of at least 75,000 pounds of fire apparatus, and shall be surfaced by either asphalt or concrete, except when alternate surfaces are approved by the Ventura County Fire Department.
- Interior circulation streets include all roadways that are considered common or primary roadways for traffic flow through the site and for fire department access serving all proposed structures. The Project would be

required to provide approved fire apparatus turnarounds on all dead-end fire apparatus access roadways over 150 feet in length.

- Typical interior Project roads, including collector and local roads, will be constructed to minimum code required unobstructed widths and shall be improved with aggregate cement or asphalt paving materials. The primary interior circulation road will be designed to accommodate a minimum of at least 75,000-lb. fire apparatus load.
- Buildings exceeding 30 feet in height shall be provided with aerial fire apparatus access. One or more of the required access routes shall be located not less than 15 feet and not more than 30 feet from the building(s), to the approval of the fire code official.
- Private and public streets shall meet all project approved fire code requirements and/or mitigated exceptions for maximum allowable dead-end distance, paving, and fuel management prior to combustibles being brought to the site.
- Vertical clearance of vegetation (lowest-hanging tree limbs), along roadways will be maintained at clearances of 13 feet, 6 inches or more above the surface of the roadway to allow fire engines passage. Unobstructed vertical clearance must be clear to the sky for aerial fire apparatus access roadways to allow aerial ladder truck operation.
- Cul-de-sacs and fire apparatus turnarounds will meet requirements and VCFD Standards.
- Roadways and/or driveways will provide fire department access to within 150 feet of all portions of the exterior walls of the first floor of each structure.
- Roadway design features (e.g., speed bumps, humps, speed control dips, planters, and fountains) are designed to reduce speed. Therefore, they impede the response of emergency vehicles and increase estimated travel times into an area. The Ventura County Fire Department does not encourage speed bumps as a mitigation to reduce speed. As such, the Project will use alternatives such as stop signs, speed limit signs, and street design.
- Access roads shall be completed and paved prior to issuance of building permits and prior to the occurrence of combustible construction.
- Developer will provide information illustrating the new roads, in a format acceptable to the VCFD for updating of Fire Department's response maps.

5.1.2 Circulation and Road Width

Circulation within the community is provided by roads that meet aerial fire apparatus standards, and provides vehicular circulation to the proposed units, as well as resident parking spaces. The proposed parcels will be granted access easements over the proposed roads, to ensure complete site circulation. The proposed residential units are clustered, overlooking core community spaces such as play fields, playgrounds, and community centers. Internal pathways provide pedestrian circulation to residential buildings and community amenities within the site.

The fire apparatus access roadways will be constructed to current VCFD Standard 501 and 2022 CFC requirements, including minimum 30-foot unobstructed road width (two Phase One resident parking driveways for parking access will be 25' and 26' wide), with parking restrictions on both sides, unless deemed otherwise by the VCFD. All curves in Fire Department Access Roads shall have no less than a centerline horizontal radius curvature of 40 feet turning radius for emergency equipment. All intersections will have a minimum of 25 feet unobstructed roadway width to ensure fire apparatus turning access.

5.1.3 Maximum Dead-End Road (cul-de-sac) Length

The Project has two entrances which connect to a looping internal circulation system and an emergency access/egress roadway. Dead end streets longer than 150 feet shall have approved provisions for fire apparatus access; however, no streets in the current design exceed 150 feet. Fire apparatus turnarounds to include turning radius widths approved by VCFD.

5.1.4 Gates

No gates are proposed aside from the emergency access roadway gate that will be equipped with a Knox box/key switch. If any gates are to be installed they are subject to Fire Code requirements and standards.

5.1.5 Premises Identification

Identification of roads and structures will comply with VCFD Fire Prevention Standard 502, as follows:

- Multi-family residential buildings shall have address numbers installed to meet the following requirements:
  (1) The minimum height of the numbers shall be 10-inches.
  (2) The minimum width of each number shall be 5-inches.
  (3) The minimum stroke width of each number shall be 1-inch
- Where buildings are set back from the street, larger numbers may be required as determined by the Fire District. To calculate the required width and stroke width of each number, the following shall apply: width = 1/2 of the required height and stroke width = 1/10 of the required height.
- Each individual unit shall have its address/unit number above or adjacent to the entrance door.
- Complexes with multiple buildings may be required to provide address range posted at driveway entrances, directories, premises maps, and directional signs at locations approved by the Fire District.
- When directories are required by the Fire District, they shall meet the following requirements:
  (1) Provided at every entrance into the complex.
  (2) Setback two (2) feet from the curb and face the driveway.
  (3) Minimum size shall be 3-feet by 2-feet.
  (4) Indicate location of all buildings on the property.
  (5) Building numbers shall be a minimum of 3/8-inch in height.
  (6) Individual unit numbers shall be a minimum of 1/4-inch in height.
  (7) Lettering shall be a minimum of 1/2-inch in height.
  (8) Illuminated either internally or externally.

5.1.6 Ongoing Infrastructure Maintenance

Project Owner/Property Management Company shall be responsible for long-term funding and maintenance of internal private roads.

5.1.7 Pre-Construction Requirements

Prior to bringing lumber or combustible materials onto the Project site, site improvements within the active development area shall be in place, including utilities, operable fire hydrants, an approved, temporary roadway surface, and fuel modification zones established. These features will be approved by the fire department their designee prior to combustibles being brought on-site.

5.2 Ignition-Resistant Construction

All new structures will be constructed to Ventura County Building and Fire Code standards, and 2022 CBC/CFC standards (or then current edition). Each of the proposed dwelling units will comply with the enhanced ignition-resistant construction standards of the 2022 California Building Code, Chapter 7A. These requirements address roofs, eaves, exterior walls, vents, appendages, windows, and doors and result in hardened structures that have been proven to perform at high levels (resist ignition) during the typically short duration of exposure to burning vegetation from wildfires. (See Appendix D for specific Ignition-Resistant Construction Requirements.)

There are two primary concerns for structure ignition: 1) radiant and/or convective heat and 2) burning embers (NFPA 1144 2008, Ventura County Fire Protection District 2011, IBHS 2008, and others). Burning embers have been a focus of building code updates for at least the last decade, and new structures in the WUI built to these codes have proven to be very ignition resistant. Likewise, radiant and convective heat impacts on structures have been minimized through CBC Chapter 7A exterior fire ratings for walls, windows and doors. Additionally, provisions for modified fuel areas separating wildland fuels from structures have reduced the number of fuel-related structure losses. As such, most of the primary components of the layered fire protection system provided the project are required by VCFD and state codes, but are worth listing because they have been proven effective for minimizing structural vulnerability to wildfire and, with the inclusion of required interior sprinklers (required in the 2022 CBC and 2022 CFC updates), of extinguishing interior fires, should embers succeed in entering a structure. Even though these measures are now required by the latest Building and Fire Codes, at one time, they were used as mitigation measures for buildings in WUI areas, because they were known to reduce structure vulnerability to wildfire. These measures performed so well, they were adopted into the code. The following project features are required for new development in WUI areas and form the basis of the system of protection necessary to minimize structural ignitions as well as providing adequate access by emergency responders:

1. Application of Chapter 7A, ignition resistant building requirements
2. New class-A fire rated roof and associated assembly. With the proposed class-A fire rated roof, there will be attic or void spaces above the living spaces requiring ventilation to the outside environment. The attic spaces will require either ember-resistant roof vents or a minimum 1/16-inch mesh (smaller sizes restrict air flow) and shall not exceed 1/8-inch mesh for side ventilation (recommend BrandGuard, O'Hagin or similar vents). Minimum vent size is provided as smaller mesh may result in ventilation issues. All vents used for this project will be approved by VCFD.

3. Multi-pane glazing with a minimum of one tempered pane, fire-resistance rating of not less than 20 minutes when tested according to NFPA 257 (such as SaftiFirst, SuperLite 20-minute rated glass product), or be tested to meet the performance requirements of State Fire Marshal Standard 12-7A-2
4. Automatic, interior fire sprinkler system to code for all residential dwellings and attached garages.
5. Modern infrastructure, access roads, and water delivery system.

5.3 Fire Protection Systems

5.3.1 Water Supply

The Project will be served domestic water by Ventura Water. There are currently two water meters serving the property, a 4-inch agricultural meter and a 3/4-inch domestic meter. In March 2022, the water supplied to the agricultural meter was changed from non-potable to potable water by Ventura Water. Since that time the property owner has been paying potable water rates for irrigation even though the meter is still considered an agricultural meter. Since the site is outside of the City of Ventura, an Out of Area Service Agreement for water service will need to be approved by LAFCo. [18]

5.3.2 Hydrants

Hydrants shall be located along fire access roadways as determined by the VCFD (Standard 14.5.3) to meet operational needs on fire access roadways in compliance with Appendix C of the 2022 CFC (or then current edition) for multi-family residential. Fire hydrants will be consistent with applicable Design Standards.

5.3.3 Fire Sprinklers

All structures will be protected by an automatic, residential fire sprinkler system. Automatic fire sprinklers systems shall be in accordance with VCFD requirements and the applicable National Fire Protection Association (NFPA) standards. Fire sprinkler systems will be remotely supervised by an approved 24/7 central-station (NFPA 71). Fire sprinkler monitoring plans for each building will be submitted to VCFD for approval before installation.

5.4 Defensible Space and Vegetation Management

5.4.1 Defensible Space

Wildland-urban interface (WUI) fire protection requires a holistic approach, which includes the components of infrastructure and water, structural safeguards (addressed in this FPP), and adequate defensible space setbacks. This section provides defensible space details for the Project.

5.4.2 Fuel Modification Zone Requirements

A fuel modification zone (FMZ) is a strip of land where combustible vegetation has been removed and/or modified and partially or totally replaced with more adequately spaced, drought-tolerant, fire resistant plants in order to

[18] Project Summary, Jensen Design & Survey, 2025

provide a reasonable level of protection to structures from wildland fire. A typical landscape/fuel modification zone consists of a 100-foot-wide fuel management zone from each structure extending outward towards undeveloped areas.

Cohen (1995) performed structure ignition fire research studies that suggest, as a rule-of-thumb, larger flame lengths and widths require wider fuel modification zones to reduce structure ignition. For example, valid Structure Ignition Assessment Modeling results indicate that a 20-foot-high flame has minimal radiant heat to ignite a structure (bare wood) beyond 33 feet (horizontal distance). Whereas a 70-foot-high flame requires about 130 feet of clearance to prevent structure ignitions from radiant heat (Cohen and Butler 1996). For this fire study example, bare wood was used, which is more combustible unlike the exterior wall designs to be implemented on the proposed buildings.

Based on the Project's site plan, the Project site achieves 100 feet or more of FMZ, which consists of asphalt roadways and parking stalls, and a fully irrigated landscape. Due to less than 1,000 feet of separation between the two primary points of access for the Project, an additional 100 feet of FMZ will be provided as an additional fire protection measure. A total of 200 feet of FMZ is provided as discussed below.

The conceptual FMZ map is presented graphically for the Project in Figure 5 (Fuel Modification Zones). Vegetation management will also be implemented as an interim FMZ throughout the construction phases for each structure as there may be a period where the development is exposed to wildland fuels. FMZs will be implemented according to the VCFD requirements for the entire Project.

5.4.2.1 Fuel Modification Zone Standards

The purpose of this section is to document VCFD's requirements and make them available for reference. The applicable FMZ design features from VCFD Standard 515 include the following:

> A typical landscape/fuel modification installation consists of a 100-foot-wide fuel management zone from each structure extending outward towards undeveloped areas. The Project will be providing 200 feet of vegetation fuel modification and management. The fuel modification area is provided by the use of zones described below.[19]
>
> **ZONE 0 – Non-Combustible Zone 0-5 Feet.** Zone 0 extends 5 feet from structures, outbuildings, attached decks and stairs. The non-combustible zone is designed to prevent embers from igniting fires adjacent to structures, which even though generally small, can spread fire to a building or structure. Vegetation landscaping, natural fiber mulch, and other combustibles items are prohibited in this zone.
>
> **ZONE 1 – Transitional Area 5-30 Feet.** Zone 1 extends 5-30 feet from buildings and structures and reduces the likelihood of fire burning directly to the structure.
>
> Zone 1 is the intermediate zone that reduces the likelihood of fire burning directly to the structure. This is accomplished by modifying fuels and creating a discontinuity between planting groups that limits the pathways for fire to burn to the structure and reduces the potential for near-to-building

[19] Ventura County Fire Department, Guidelines 424 and 515

ember generation and radiant heat exposures. An additional purpose of this zone is to provide a defendable area for fire personnel to stage and take direct action.

ZONE 2 – Extended Zone 30-100 Feet. Zone 2 extends 30-100 feet from buildings or structures.

Zone 2 is the extended zone and is designed to reduce the potential behavior of an oncoming fire in such a way as to drop an approaching fire from the crown of trees to the ground, reducing the flame heights, and the potential for ember generation and radiant heat exposure to structures. Additional benefits of Zone 2 include facilitating direct defense actions and improving the function of Zones 0 and 1. Zone 2 is the area from the outer edge of Zone 1 to 100 feet from structures and decks.

ZONE 3 – Thinning Zone 100-200 Feet. Zone 3 is considered a thinning zone and is any FMZ greater than 100 feet from structures and decks.

When provided, either by conditions of development, voluntary by the property owner, or required by the Fire Department, this zone is more of a progressive thinning zone to lessen spread of fire as it approaches the primary FMZ adjacent to structures. The amount of fuel reduction and removal should take into consideration the type and density of fuels, aspect, topography, weather patterns, and fire history. Typical fuel reduction in Zone 3 is 50% thinning from 100 to 150 feet and 30% thinning from 150 to 200 feet.

5.4.2.2 Conceptual Fuel Modification Zone Description

The proposed FMZ occurs around the perimeter of the Project and will be 200 feet extending outward from buildings. All highly flammable native vegetation shall be removed or thinned in accordance with VCFD Standard 515. The landscaped areas of the FMZ will be planted with drought-tolerant, fire-resistant vegetation. The Project's plant palette will be approved by the VCFD. A permanent, automatic irrigation system will be installed within the irrigated portions of the FMZ to maintain hydrated plants. The interior landscaped areas of the Project will meet FMZ standards.

Proposed for the Project is a site-specific fuel modification zone program, described in detail below, with additional measures that are consistent with the intent of VCFD Standard 515. The Standard is consistent with Chapter 49 of the 2022 California Fire Code, Government Code 51175 – 51189, and Public Resources Code 4291, which require that fuel modification zones be provided around every building that is designed primarily for human habitation or use.

Zone 0 – Non-Combustible Zone: 0 to 5 feet from a structure.

- Non-combustible surface (pavement, concrete, decomposed granite, etc.) or other non-combustible materials. Combustible ground covers, such as mulch, wood chips, and natural or artificial turf are prohibited adjacent to structures. Storage of combustible materials and products is prohibited in this zone.

Zone 1 – Transitional Area: 5 to 30 feet from a structure.

- Zone 1 is applicable site wide and is an irrigated, limited planting area measured from the outermost edge of the structure outward to 30 feet (horizontal), or to the property line in all directions.

- Irrigated wet zone (water conserving irrigation systems with efficient drip emitters and “smart” controllers and use of California Friendly landscape concepts)
- Minimum 3-foot wide pathway shall be provided around and abutting any structures for firefighter access.
- No tree crowns within 10 feet of structures (at maturity)
- Tree spacing of a minimum 10 feet between crowns
- No tree limb encroachment within 10 feet of a structure or chimney, including outside barbecues or fireplaces
- Year-round maintenance
- Fire-resistive species composition
- No combustible fencing
- Landscape Plan prepared and submitted in compliance with this plan.

Zone 2 – Extended Zone: 30 to 100 feet from a structure.

- Zone 2 is applicable site wide and is an irrigated area measured horizontally from the outer edge of Zone 1 to 100 feet from the structure or property line, whichever is first.
- This zone includes ground cover and shrub plantings.
- Limited trees of a very fire resistive type and additional spacing.
- Trees spaced to allow a minimum 10-foot clearance to structure at full maturity.
- Zone 2 can be planted with slightly higher plant density than Zone 1 as long as landscape does not create any horizontal or vertical fuel ladders (e.g., fuel which can spread fire from ground to trees).

Zone 3 –Thinning Zone: 100 to 200 feet from a structure.

- Zone 3 is applicable east of the Project and adjacent to the Norway Tract (Valley Vista community) on the open space parcel and measured horizontally from the structures.
- This zone is a progressive thinning zone to lessen the spread of fire as it approaches the primary FMZ adjacent to structures.
- Selective thinning for fuel reduction ranges from 30% to 50% of native vegetation/fuels.

5.4.3 Road and Driveway Hazard Abatement

In accordance with VCFD standards, all roads and driveways within or adjacent to the Project site will be provided with roadside vegetative fuel modification, which includes complete clearing of all grass and brush to a distance of 10 feet on each side of all access roads and driveways.

5.4.4 Prohibited Plants

Certain plants are considered prohibited in the landscape due to characteristics that make them highly flammable. These characteristics can be physical (structure promotes ignition or combustion) or chemical (volatile chemicals increase flammability or combustion characteristics). The plants included in the Prohibited Plant List (Appendix E) are unacceptable from a fire safety standpoint and will not be planted on the Project site or allowed to establish opportunistically within fuel modification zones or landscaped areas.

5.4.5 Construction Phase Vegetation Management

Vegetation management requirements shall be implemented at commencement and throughout the construction phase. Vegetation management shall be performed pursuant to the FAHJ on all building locations prior to the start of work and prior to any import of combustible construction materials. Adequate fuel breaks shall be created around all grading, site work, and other construction activities in areas where there is flammable vegetation.

5.4.6 Annual Fuel Modification Zone Compliance Inspection

To confirm that the Project's FMZs and landscaped areas are being maintained according to VCFD standards and the provisions of this FPP, VCFD inspectors, or a mutually agreed upon third party, will perform an annual inspection. If the FMZ areas are not compliant, the property owner or management company will have a specified period to correct any noted issues so that a re-inspection can occur and certification of compliance can be achieved.

6 Wildfire Education Program

The residents of the Project will be provided a proactive educational component disclosing the potential wildfire risk and this report's requirements. This educational information must include maintaining the landscape and structural components according to the appropriate standards and embracing a "Ready, Set, Go"[20] stance on evacuation which involves the preparation of a Wildfire Action Plan for each household in the event evacuation is necessary. The VCFD provides basic wildfire safety information at: https://www.readyventuracounty.org/wildfire/.

> Ventura County utilizes a state-of-the-art emergency notification system to deliver time-sensitive emergency alerts in English and Spanish to areas within Ventura County where there is a threat to health and safety.[21]
>
> These messages may include, but are not limited to evacuation warnings or orders, severe weather advisories, community policing incidents, searches for missing at-risk individuals and public health alerts.
>
> VC Alerts can only be sent to locations within Ventura County. To receive alerts by phone, text, email, fax, TTY/TDD device, or numeric page for your home, work or loved one's location, register by one of the methods below:
>
> Internet: www.vcalert.org
> Email: vc.alert@ventura.org
> Phone: 805.648.9283

INTENTIONALLY LEFT BLANK

7 Recommendations

The fire protection measures are evaluated to provide at least equivalent protection based on the experience of the preparers of this report.

1. Construct all buildings in accordance with CBC Chapter 7A building code requirements.
2. Maintain two ingress/egress points on North Ventura Avenue and an emergency vehicle access (EVA) connection to Floral Drive in the Norway Tract / Valley Vista community to the north.
3. Install Fuel Modification Zones (FMZs) consisting of Zone 0, Zone 1, and Zone 2 fuel modification and vegetation management around the buildings and in the common areas of the Project (see Fuel Modification Plan).
4. Conduct FMZ inspections annually, performed by VCFD, the property manager, or a mutually agreed upon 3rd party to their satisfaction. This measure will ensure that the FMZs are functioning as intended.
5. Prepare a Construction Site Safety Plan and Fire Department Site Access Plan for each phase of development.
6. The Project developer, or successor owner, will retain ownership of the property as a rental community, with complete control and responsibility for all maintenance.

The fire protection challenges associated with a Fire Hazard Severity Zone (FHSZ) have been addressed in this plan. Compliance with applicable codes and VCFD standards has been documented. The fact that a project is proposed for an area designated as FHSZ does not indicate that an area or the project is not safe for development. It does indicate that specific fire protection features that minimize structure vulnerability will be required. The materials and construction methods for exterior wildfire exposure have been included in this plan and will be applied to the Project. Similarly, the required vegetation management and defensible space applicable to projects in a FHSZ have been included in the plan and will be applied to the Project.

INTENTIONALLY LEFT BLANK

8 Conclusion

This FPP for the Ventura Ranch Farmworker Housing project (Project) documents how the Project conforms with required fire and building codes. It also provides guidance for vegetation maintenance for the proposed FMZs and landscaped areas on the Project site. The requirements and recommendations provided in this FPP have been designed specifically for the Project. This analysis and its fire protection justifications are supported by fire science research, results from previous wildfire incidents, and fire agencies that have approved these concepts. The Project design features, asphalt roads and parking stalls, fully irrigated landscaping, and defensible space up to 200 feet from structures provides a reasonable level of safety for the Project.

Ultimately, it is the intent of this FPP to guide the fire protection efforts for the Project in a comprehensive manner. Implementation of the measures detailed in this FPP will reduce the risk of wildfire at the Project site and will improve the ability of firefighters to fight fires on the properties and protect property and neighboring resources, irrespective of the cause or location of ignition.

It must be noted that during extreme fire conditions, there are no guarantees that a given structure will not burn. Precautions and minimizing actions identified in this report are designed to reduce the likelihood that fire will impinge upon the Project assets or threaten its occupants or visitors. Additionally, there are no guarantees that fire will not occur in the area or that fire will not damage property or cause harm to persons or their property. Implementation of the required enhanced construction features provided by the applicable codes and the fuel modification requirements provided in this FPP will reduce the Project site's vulnerability to wildfire. It will also help accomplish the goal of this FPP to assist firefighters in their efforts to defend structures.

It is recommended that the Project maintain a conservative approach to fire safety. This approach must include maintaining the landscape and structural components according to the appropriate standards and embracing a "Ready, Set, Go!" stance on evacuation. The Project is not to be considered a shelter-in-place development. However, the fire agencies and/or law enforcement officials may, during an emergency, determine that it is safer to temporarily shelter residents or visitors on the Project site. When an evacuation is ordered, it will occur according to pre-established evacuation decision points or as soon as notice to evacuate is received. Fire is a dynamic and somewhat unpredictable occurrence; it is important for anyone living at the wildland-urban interface to educate themselves on practices that will improve safety.

BehavePlus Fire Behavior Analysis

1 Fire Behavior Modeling

Background

Fire behavior modeling has been used by researchers for approximately 50+ years to predict how a fire will move through a given landscape (Linn 2003). The models have had varied complexities and applications throughout the years. One model has become the most widely used for predicting fire behavior on a given landscape. That model, known as "BEHAVE," was developed by the U. S. Government (USDA Forest Service, Rocky Mountain Research Station) and has been in use since 1984. Since that time, it has undergone continued research, improvements, and refinement. The current version, BehavePlus, V6, includes the latest updates incorporating years of research and testing. Numerous studies have been completed testing the validity of the fire behavior models' ability to predict fire behavior given site specific inputs. One of the most successful ways the model has been improved has been through post-wildfire modeling (Brown 1972, Lawson 1972, Sneeuwjagt and Frandsen 1977, Andrews 1980, Brown 1982, Rothermel and Rinehart 1983, Bushey 1985, McAlpine and Xanthopoulos 1989, Grabner, et. al. 1994, Marsden-Smedley and Catchpole 1995, Grabner 1996, Alexander 1998, Grabner et al. 2001, Arca et al. 2005). In this type of study, BehavePlus is used to model fire behavior based on pre-fire conditions in an area that recently burned. Real-world fire behavior, documented during the wildfire, can then be compared to the prediction results of BehavePlus and refinements to the fuel models incorporated, retested, and so on.

Fire behavior modeling includes a high level of analysis and information detail to arrive at reasonably accurate representations of how wildfire would move through available fuels on a given site. Fire behavior calculations are based on site specific fuel characteristics supported by fire science research that analyzes heat transfer related to specific fire behavior. Predicting wildland fire behavior is not an exact science. As such, the minute-by-minute movement of a fire will probably never be predictable, especially when considering the variable state of weather and the fact that weather conditions are typically estimated from forecasts made many hours before a fire. Nevertheless, field-tested and experienced judgment in assessing the fire environment, coupled with a systematic method of calculating fire behavior yields surprisingly accurate results. To be used effectively, the basic assumptions and limitations of fire behavior modeling applications must be understood.

1. First, it must be realized that the fire model describes fire behavior only in the flaming front. The primary driving force in the predictive calculations is the dead fuels less than 0.25 inches in diameter. These are the fine fuels that carry fire. Fuels greater than one inch have little effect, while fuels greater than three inches have no effect on fire behavior.
2. Second, the model bases calculations and descriptions on a wildfire spreading through surface fuels that are within six feet of the ground and contiguous to the ground. Surface fuels are often classified as grass, brush, litter, or slash.
3. Third, the software assumes that weather and topography are uniform. However, because wildfires almost always burn under non-uniform conditions, creating their own weather, length of projection period and choice of fuel model must be carefully considered to obtain useful predictions.
4. Fourth, fire behavior computer modeling systems are not intended for determining sufficient fuel modification zone/defensible space widths. However, it does provide the average length of the flames, which is a key element for determining defensible space distances for minimizing structure ignition.

Although BehavePlus has limitations, it can still provide valuable fire behavior predictions, which can be used as a tool in the decision-making process. In order to make reliable estimates of fire behavior, one must understand the relationship of fuels to the fire environment and be able to recognize the variations in these fuels. Natural fuels are made up of the various components of vegetation, both live and dead, that occur in a particular landscape. The type and quantity will depend upon soil, climate, geographic features, and fire history. The major fuel groups of grass, shrub, trees, and slash are defined by their constituent types and quantities of litter and duff layers, dead woody material, grasses and forbs, shrubs, regeneration, and trees. Fire behavior can be predicted largely by analyzing the characteristics of these fuels. Fire behavior is affected by seven principal fuel characteristics: fuel loading, size and shape, compactness, horizontal continuity, vertical arrangement, moisture content, and chemical properties.

2 Modeling Inputs

2.1 Fuels

The seven fuel characteristics help to define the 13 standard fire behavior fuel models (Anderson 1982). According to the model classifications, fuel models used for fire behavior modeling (BehavePlus) have been classified into four groups, based upon fuel loading (tons/acre), fuel height, and surface-to-volume ratio. Observation of the fuels in the field (on site) determines which fuel models should be applied in modeling efforts. The following describes the distribution of fuel models among general vegetation types for the standard 13 fuel models:

- Grasses Fuel Models 1 through 3
- Brush Fuel Models 4 through 7
- Timber Fuel Models 8 through 10
- Logging slash Fuel Models 11 through 13.

In addition, the aforementioned fuel characteristics were utilized in the recent development of 40 additional fire behavior fuel models (Scott and Burgan 2005) developed for refining use of the BehavePlus modeling system. These models attempt to improve the accuracy of the 13 standard fuel models outside of severe fire season conditions, and to allow for the simulation of fuel treatment prescriptions. The following describes the distribution of fuel models among general vegetation types for the 40 new fuel models:

- Non-burnable Models NB1, NB2, NB3, NB8, NB9
- Grass Models GR1 through GR9
- Grass shrub Models GS1 through GS4
- Shrub Models SH1 through SH9
- Timber understory Models TU1 through TU5
- Timber litter Models TL1 through TL9
- Slash blowdown Models SB1 through SB4.

For each fire behavior analyses, fuel model assignments are based on observed field conditions. As is customary for this type of analysis, the terrain and fuels directly adjacent to the proposed development are used for

determining flame lengths and fire spread. It is these fuels that would have the potential to affect a project's structures from a radiant and convective heat perspective, as well as from direct flame impingement.

Fuel beds, including grass, shrubs, timber and slash, may be observed on and adjacent to a proposed development. Often fuel types may produce flying embers that could affect a project; defenses can be built into a project design to minimize ember generation and potential impact. In most instances, various combinations of fuels are observed and the predominate fuel likely to carry the flaming front of a wildfire determined the fuel model selected.

Modeling of the site is also conducted for post-development recommendations for this project, including fuel treatment proposed as part of the site preparation and ongoing vegetation management. Fuel modification usually includes routine vegetation management around structures, improvements, alongside roadways, and infrastructure, as well as the project periphery.

2.2 Weather

Analyses are conducted for conservative, worst case, 90th percentile weather condition scenarios. Fuel moisture and wind speed information data is incorporated into the BehavePlus modeling runs. The input wind speed and direction is roughly an average surface wind at 20 feet above the vegetation over the analysis area.

2.3 Slope

Slope is a measure of angle in degrees from horizontal and can be presented in units of degrees or percent. Slope is important in fire behavior analysis as it affects the exposure of fuel beds. Additionally, fires burning uphill spread faster than those burning on flat terrain or downhill as uphill vegetation is pre-heated and dried in advance of the flaming front, resulting in faster ignition rates. For the BehavePlus analysis, slope values are determined by field observation and use of topographical data at the locations selected for each modeling scenario.

3 BehavePlus Analysis

To objectively predict flame lengths (Figure 1), spotting (Figure 2), intensities, and spread rates, the BehavePlus V6 fire behavior modeling system (Andrews, Bevins, and Seli 2004) is used in one or more modeling scenarios and incorporates observed fuel types representing the dominant vegetative fuels, slope gradients, and wind and fuel moisture values. Modeling scenario locations are selected to better understand different fire behavior that may be experienced on or adjacent to the site.

Fuel modification includes fuel treatment proposed as part of the site preparation and ongoing vegetation management. For modeling the post-development condition, fuel model assignments are re-classified for each scenario. The fuel treatments in usually result in noticeable reductions of both flame length and intensity.

It should be noted that the results (outputs) depict values based on inputs to the BehavePlus software. Changes in slope, weather, or pockets of different fuel types are not accounted for in this analysis, but models provide a worst-case wildfire condition as part of a conservative approach. Further, this modeling analysis assumes a

correlation between the site vegetation and fuel model characteristics. Model results should be used as a basis for planning only, as actual fire behavior for a given location will be affected by many factors, including unique weather patterns, small-scale topographic variations, or changing vegetation patterns.

The Fire Suppression Information in Table B-1 pertains to interpretation of flame length and fireline intensity as it relates to fire suppression efforts. Calculated flame lengths under 4.0 feet tall, fire fighters should be able to conduct a direct attack on the fire. [See Figure 3 for a chart representation.]

Table B-1. Fire Suppression Interpretation

Flame Length (ft)	Fireline Intensity (Btu/ft/s)	Interpretations
Under 4	Under 100	Fires can generally be attacked at the head or flanks by persons using hand tools. Hand line should hold the fire.
4 to 8	100-500	Fires are too intense for direct attack on the head by persons using hand tools. Hand line cannot be relied on to hold the fire. Equipment such as dozers, pumpers, and retardant aircraft can be effective.
8 to 11	500-1000	Fires may present serious control problems -- torching out, crowning, and spotting. Control efforts at the fire head will probably be ineffective.
Over 11	Over 1000	Crowning, spotting, and major fire runs are probable. Control efforts at head of fire are ineffective.

Ignition-Resistant Construction Requirements

As of the date of this fire protection plan, the following are the requirements for ignition resistant construction for The Proposed Project, including requirements under Chapter 7A of the California Building Code (CBC). In addition, exterior building construction including roofs, eaves, exterior walls, doors, windows, decks, and other attachments must meet the most current CBC Chapter 7A ignition resistance requirements at the time of building permit application.

1. All structures will be built with a Class A roof assembly, including a Class A roof covering. Roofs shall have a roofing assembly installed in accordance with its listing and the manufacturer's installation instructions.
2. Where the roof profile allows a space between the roof covering and roof decking, the spaces shall be constructed to prevent the intrusion of flames and embers, be fire stopped with approved materials or have one layer of minimum 72 pound mineral-surfaced non-perforated cap sheet complying with ASTM D 3909 installed over the combustible decking. However, openings on barrel tiles or similar roof coverings, must be fire stopped (bird stopped) with approved materials to prevent the accumulation of debris, bird nests, etc. between the tiles and decking material.
3. When provided, exposed valley flashings shall be not less than 0.019-inch (No. 26 galvanized sheet gage) corrosion-resistant metal installed over a minimum 36-inch-wide underlayment consisting of one layer of minimum 72 pound mineral-surfaced non-perforated cap sheet complying with ASTM D 3909 running the full length of the valley.
4. All rain gutters, downspouts and gutter hardware shall be constructed from metal or other non-combustible material to prevent wildfire ignition along eave assemblies.
5. All chimney, flue or stovepipe openings attached to a fireplace, stove, or other solid or liquid fuel burning equipment or device shall be equipped with an approved spark arrester. An approved spark arrester is defined as a device intended to prevent sparks from escaping into the atmosphere and constructed of nonflammable materials, having a 12-gauge minimum thicknesses with openings no greater than ½ inch, or other approved alternative material determined to provide equal or better protection. It shall be installed to be visible for the purposes of inspection and maintenance.
6. The exterior surface materials shall be non-combustible, including hard or ignition resistant, such as stucco. In all construction, exterior walls shall extend from the top of the foundation to the roof and terminate at 2-inch nominal solid blocking between rafters at all roof overhangs, or in the case of enclosed eaves, terminate at the enclosure.
7. All eaves, fascias, and soffits will be enclosed (boxed) with non-combustible materials. This shall apply to the entire perimeter of each structure. Eaves of heavy timber construction are not required to be enclosed as long as attic venting is not installed in the eaves. For the purposes of this section, heavy timber construction shall consist of a minimum of 4"x 6" rafter tails.
8. Paper-faced insulation shall be prohibited in attics or ventilated spaces.
9. Automatic interior fire sprinklers for commercial buildings shall be installed according to the National Fire Protection Association (NFPA) 13 requirements.
10. Roof vents, dormer vents, gable vents, foundation ventilation openings, ventilation openings in vertical walls, or other similar ventilation openings shall be louvered and covered with 1/16-inch, noncombustible, corrosion-resistant metal mesh or other approved material that offers equivalent protection.
11. Attic or foundation ventilation louvers or ventilation openings in vertical walls shall not exceed 144 square inches per opening and shall be covered with 1/16" inch mesh corrosion-resistant metal screen or other approved material that offers equivalent protection. Ventilation louvers and openings may be incorporated as part of access assemblies.

12. No attic ventilation openings or ventilation louvers shall be permitted in soffits, in eave overhangs, between rafters at eaves, or in other overhanging areas.
13. All fences and gate assemblies (fences, gates, and fence posts) attached or within five feet of a structure shall be of non-combustible material or pressure-treated exterior fire-retardant wood.
14. All projections (exterior balconies, decks, patio covers, unenclosed roofs and floors, and similar architectural appendages and projections) or structures less than five feet from a building shall be of non-combustible material, one-hour fire resistive construction on the underside, heavy timber construction, pressure-treated exterior fire- retardant wood or ignition resistant construction. When such appendages and projections are attached to exterior fire- resistive walls, they shall be constructed to maintain same fire-resistant standards as the exterior walls of the structure.
15. Accessory structures attached to buildings with habitable spaces and projections shall be in accordance with Chapter 7A of the CBC.
16. Detached accessory structures located less than 50 feet from a building containing habitable space shall be constructed in accordance with Chapter 7A of the CBC.
    - **Exception:** Accessory structures less than 120 square feet in floor area located at least 30 feet from a building containing a habitable space.
17. Exterior doors shall be approved non-combustible construction, solid core wood and shall conform to the performance requirements of standard SFM 12-7A-1 or shall be of approved noncombustible construction, or solid core wood having stiles and rails not less than 1⅜ inches thick with interior field panel thickness no less than 1¼ inches thick, or shall have a fire-resistance rating of not less than 20 minutes when tested according to National Fire Protection Association (NFPA) 252.
18. All glass or other transparent, translucent or opaque glazing materials, that is used in exterior windows, including skylights, or exterior glazed door assemblies shall be constructed of multipane glazing with one tempered pane meeting the requirements of Section 2406 (2016 CBC) Safety Glazing.
19. Vinyl window assemblies are deemed acceptable if the windows have the following characteristics:
    - Frame and sash are comprised of vinyl material with welded corners
    - Metal reinforcements in the interlock area
    - Glazed with insulating glass, annealed or tempered (one layer of which must be tempered glass).
    - Frame and sash profiles are certified in AAMA Lineal Certification Program.
    - Certified and labeled to ANSI/AAMA/NWWDA 101/LS2-97 for Structural Requirements.

Appendix E

Fuel Modification Zone Prohibited Plants List

Botanical Name	Common Name	Comment*
Trees		
Abies species	Fir	F
Agonis juniperina	Juniper Myrtle	F
Casuarina cunninghamiana	River She-Oak	F
Chamaecyparis species (numerous)	False Cypress	F
Cryptomeria japonica	Japanese Cryptomeria	F
Cupressocyparis leylandii	Leyland Cypress	F
Cupressus species *(C. fobesii, C. glabra, C. sempervirens,)*	Cypress (Tecate, Arizona, Italian, others)	F
Eucalyptus species (numerous)	Eucalyptus	F, I
Juniperus species (numerous)	Juniper	F
Lithocarpus densiflorus	Tan Oak	F
Melaleuca species *(M. linariifolia, M. nesophila, M. quinquenervia)*	Melaleuca (Flaxleaf, Pink, Cajeput Tree)	F, I
Picea (numerous)	Spruce	F
Palm species (numerous)	Palm	F, I
Pinus species *(P. brutia, P. canariensis, P. b. eldarica, P. halepensis, P. pinea, P. radiata, numerous others)*	Pine (Calabrian, Canary Island, Mondell, Aleppo, Italian Stone, Monterey)	F
Platycladus orientalis	Oriental arborvitae	F
Pseudotsuga menziesii	Douglas Fir	F
Tamarix species *(T. africana, T. aphylla, T. chinensis, T. parviflora)*	Tamarix (Tamarisk, Athel Tree, Salt Cedar, Tamarisk)	F, I
Taxodium species *(T. ascendens, T. distichum, T. mucronatum)*	Cypress (Pond, Bald, Monarch, Montezuma)	F
Taxus species *(T. baccata, T. brevifolia, T. cuspidata)*	Yew (English, Western, Japanese)	F
Thuja species *(T. occidentalis, T. plicata)*	Arborvitae/Red Cedar	F
Groundcovers, Shrubs and Vines		
Acacia species	Acacia	F, I
Adenostoma fasciculatum	Chamise	F
Adenostoma sparsifolium	Red Shanks	F
Agropyron repens	Quackgrass	F, I
Anthemis cotula	Mayweed	F, I
Arctostaphylos species	Manzanita	F
Arundo donax	Giant Reed	F, I
Artemisia species *(A. abrotanium, A. absinthium, A. californica, A. caucasica, A. dracunculus, A. tridentata, A. pynocephala)*	Sagebrush (Southernwood, Wormwood, California, Silver, True tarragon, Big, Sandhill)	F
Atriplex species (numerous)	Saltbush	F, I
Avena fatua	Wild Oat	F
Baccharis pilularis	Coyote Bush	F
Bambusa species	Bamboo	F, I
Bougainvillea species	Bougainvillea	F, I
Brassica species *(B. campestris, B. nigra, B. rapa)*	Mustard (Field, Black, Yellow)	F, I
Bromus rubens	Foxtail, Red brome	F, I

Botanical Name	Common Name	Comment*
Castanopsis chrysophylla	Giant Chinquapin	F
Cardaria draba	Hoary Cress	I
Cirsium vulgare	Wild Artichoke	F,I
Conyza bonariensis	Horseweed	F
Coprosma pumila	Prostrate Coprosma	F
Cortaderia selloana	Pampas Grass	F, I
Cytisus scoparius	Scotch Broom	F, I
Eriogonum species *(E. fasciculatum)*	Buckwheat (California)	F
Fremontodendron species	Flannel Bush	F
Heterotheca grandiflora	Telegraph Plant	F
Hordeum leporinum	Wild barley	F, I
Juniperus species	Juniper	F
Lactuca serriola	Prickly Lettuce	I
Larrea tridentata	Creosote bush	F
Lolium multiflorum	Ryegrass	F, I
Lonicera japonica	Japanese Honeysuckle	F
Mimulus aurantiacus	Sticky Monkeyflower	F
Miscanthus species	Eulalie Grass	F
Muhlenbergia species	Deer Grass	F
Nicotiana species *(N. bigelovii, N. glauca)*	Tobacco (Indian, Tree)	F, I
Pennisetum setaceum	Fountain Grass	F, I
Perovskia atroplicifolia	Russian Sage	F
Phoradendron species	Mistletoe	F
Pickeringia montana	Chaparral Pea	F
Rhus (R. diversiloba, R. laurina, R. lentii)	Sumac (Poison oak, Laurel, Pink Flowering)	F
Ricinus communis	Castor Bean	F, I
Rhus Lentii	Pink Flowering Sumac	F
Salvia species (numerous)	Sage	F, I
Salsola australis	Russian Thistle	F, I
Solanum Xantii	Purple Nightshade (toxic)	I
Silybum marianum	Milk Thistle	F, I
Thuja species	Arborvitae	F
Urtica urens	Burning Nettle	F

*F = flammable, I = Invasive

Notes:

1. Plants on this list that are considered invasive are a partial list of commonly found plants. There are many other plants considered invasive that should not be planted in a fuel modification zone and they can be found on The California Invasive Plant Council's Website www.cal-ipc.org/ip/inventory/index.php. Other plants not considered invasive at this time may be determined to be invasive after further study.
2. For the purpose of using this list as a guide in selecting plant material, it is stipulated that all plant material will burn under various conditions.
3. The absence of a particular plant, shrub, groundcover, or tree, from this list does not necessarily mean it is fire resistive.
4. All vegetation used in Fuel Modification Zones and elsewhere in this development shall be subject to approval of the Fire Code Official.
5. Landscape architects may submit proposals for use of certain vegetation on a project specific basis. They shall also submit justifications as to the fire resistivity of the proposed vegetation.
